Flatbed furnaces are characterized by a single area as a supporting surface for the coffin. The ash residues in the muffle are brought into the area for completing the combustion by means of vanes. Similar to the multi-story furnace, the chamber to complete the combustion is delimited by two turntables enclosing the areas. One advantage of the flatbed furnaces is probably that they need relatively little space."

The Ruppmann Furnace (Document 109) is a typical *Etagenofen*. The furnace damper (*Ofenschieber*; 1) is topped by a fume hood (*Schwadenabsaugung*, 8) coming out of the opening of the damper. The muffle (*Hauptbrennraum*, 2) is equipped with a gas burner (B1) and at the bottom delimited by three coffin support stones (*Sargbrückensteine*, S) and is closed by the first turntable (*Drehplatte*, D1). Below it is located the second turntable (D2) and further below the third (D3). The three turntables delimit two chambers, of which the upper is the chamber to complete the combustion of the ashes (*Ascheausbrennkammer*, 3), which is equipped with an auxiliary burner (B2), and the lower is the ash-cooling chamber (*Ascheabkühlkammer*, 4). At the bottom the ashes are extracted (*Ascheentnahme*, 5). The gases developing in the muffle and in the complete combustion chamber are led into a post-combustion chamber for the fumes (*Rauchgasnachbrennkammer*, 6) equipped with an afterburner (B3). The combustion air is channeled into the muffle at various spots by means of a blower (G).

Here is the operation description of a Ruppmann Furnace at the Dresden Crematorium (Schetter/Burk 2006, p. 5):

> *"The coffin is placed in the main combustion chamber on a specially designed support grate by means of an automatic introduction machine. After closing the furnace door, the cremation as such takes place in the main combustion chamber. There the combustion process occurs by means of heat transfer between the combustion chamber walls and the coffin, and by a defined supply of primary combustion air. If necessary, the cremation process is supported by the main gas burner. The design of the furnace chamber in connection with the coffin's grate support produces an intense mixture of the combustible gases with the combustion air due to the formation of vortices. The unprocessed gases coming out of the main combustion chamber pass into a post-combustion chamber where they are burned completely by means of additional, secondary air. The required afterburner temperature is maintained by another gas burner. After about an hour, the remaining ashes are moved to the lower ash-combustion chamber where they are heat-treated. After another hour, the heat-treated ashes are brought to a cooling grate and then to the ash container."*

At the end of 1998 there were 113 crematoria in Germany with altogether 211 furnaces, 90% of which were heated with gas, 8% with electricity, and 2% with naphtha. The average duration of a cremation was 60-70 minutes (Sircar 2002, pp. 10, 15, 24).

Unit II: J.A. Topf & Söhne

and the Cremation Furnaces of Auschwitz and Birkenau

1. Historical Notes on the Topf & Söhne Company

The most-detailed account of the origins and development of the Topf Company can be found in the already-mentioned book *Industrie und Holocaust* by Annegret Schüle, especially in its Chapter I, which covers the period from 1878 to 1930.

The Topf Company was founded in 1878 by Johann Andreas Topf (1816-1891), a master brewer who also worked on improving industrial incinerators. In 1884, his son Max Julius Ernst (1859-1914) joined the company, and the following year also his other son Wilhelm Louis, called Ludwig (1863-1914), so that on April 1, 1885 the company was renamed J.A. Topf & Sons. In the following years, the other two brothers joined the company: Albert (1857-1893) in 1886 and Gustav (1853-1896) in 1888. Ludwig remained the sole owner until his death by suicide on February 15, 1914. By a tragic irony of fate, his son, who bore the same name, also took his own life on May 31, 1945. Ludwig, the father, was a proponent of cremation, which was still in its infancy in Germany at the time. Consequently, he had himself cremated after his death. The ceremony took place on February 18, 1914, at the Gotha Crematorium. His two sons, Viktor Karl Ludwig (1903-1945) and Ernst Wolfgang (1904-1979), were still children at this time and did not take over the business until the 1930s: Ernst Wolfgang in 1929, followed by Ludwig in 1931. On December 30, 1935, the two brothers reorganized the company into a limited partnership.

At the beginning of the 1920s, Topf was known not only in Germany but also abroad. At that time, the company consisted of two main departments, one responsible for the design and construction of steam-boiler plants and the other for complete malting plants. The company's activities also extended to various firing equipment, such as mechanical firing apparatus (grate feeders), preheaters for the utilization of exhaust-gas heat, forced-draft devices, chimney constructions, industrial furnaces of all kinds, and cremation furnaces. Topf was very successful with its high-performance furnace with pre-gasification shaft for the economical combustion of lignite.

In the two decades that followed, Topf developed enormously and exported its products all over the world until the eve of the Second World War.

From 1878 to 1934, the Furnace Construction Department built about 30,000 furnaces, including about 25,000 of its own designs, for which it manufactured various types of grate bars, grates and spare parts.[85]

Between 1924 and September 1937, Topf had delivered or had been contracted in 3,710 cases to deliver items relating to 22 different types of malting equipment and storage facilities to Germany and abroad, including 39 silo gassing systems, about 700 barley, green-malt and malt worm conveyors and 375 barley, green-malt and malt elevators.[86]

---

[85] Company flyer of March 1934 with the headline "*Topf-Roststäbe*". SE, 5/411 A 195.
[86] Company flyer of 1937 with the headline "*Zahlen sprechen*…". SE, 5/411 A 191.

In the field of cremation, the Topf Company began its activities on the eve of the First World War. In 1914, it built two furnaces with coke-fired gas generators at the Halle (Saale) Crematorium; another furnace of the same type was inaugurated at the Freiburg Municipal Crematorium on April 15, 1914; and another was installed at the Hirschberg Municipal Crematorium, which opened on August 22, 1915. From the early 1920s, the company began its slow but inexorable rise to become the market leader among German companies in this industry over the next two decades. By 1934, 74 cremation furnaces had been built, including three abroad (two in Moscow and one in Brussels). 29 coke-fired furnaces, 44 gas-fired furnaces and one electric furnace; four of the gas furnaces had been converted from former coke-fired furnaces. Contributing to this success was the fact that Topf soon achieved a very-advanced technological standard and manufactured high-quality equipment; it is credited with building Germany's first gas-fired cremation furnace in Dresden in 1927, as well as Germany's first electric cremation furnace, which went into operation in Erfurt in 1933. In 1934, Topf patented a new type of gas-fired furnace, the "High-performance furnace with tiltable grates D.R.P."[87] or "Topf Cremation Furnace 1934," which was also capable of using electric heating.

Topf's research activity is also evidenced by the numerous patents granted to it, especially in the 1930s, some of which – such as the post-combustion grate and tiltable grate – introduced important innovations in cremation technology.

At the beginning of the 1940s, the Topf Company had a very-complex structure. The twelve technical departments were divided into 99 sections, but these twelve departments occupied only numbers 74-85 of the company's total of 89 departments.[88]

The Topf engineers of interest in the context of the present study were:

– Kurt Prüfer, born in 1891, with the Topf Company from 1920, chief engineer since December 2, 1935,[89] director of Subdepartment DIV, furnace construction, crematoria, waste-incineration furnaces and recovery furnaces for the recovery of metals.
– Karl Schultze, born in 1900 in Berlin, with the Topf Company from 1928, chief engineer, director of Department B, which dealt with heating, ventilation and fan construction.
– Fritz Sander, born in 1876 in Leipzig, with the Topf Company from 1910, chief engineer, proxy of Department D, which in its four sub-departments was engaged in boiler and furnace construction.

During the investigation of the criminal case brought against Prüfer by the Soviets, which will be discussed below, he personally drew a chart of the Topf Company's organizational structure, which he explained in a brief explanatory

---

87 *Deutsches Reichspatentamt Patentschrift*, Patent description filed with the German Imperial Patent Office.

88 SE, 5/411 A 163, J.A. Topf & Söhne, *Organisation der Unternehmung. Katalog der Sonderakten*. See Documents 131f.

89 Prüfer was informed of the appointment in a letter dated December 2, 1935, marked "ET" (Ernst Topf). APMO, BW 30/46, p. 2.

note (see Illustration 1). According to this chart, the company was hierarchically structured as follows:[90]

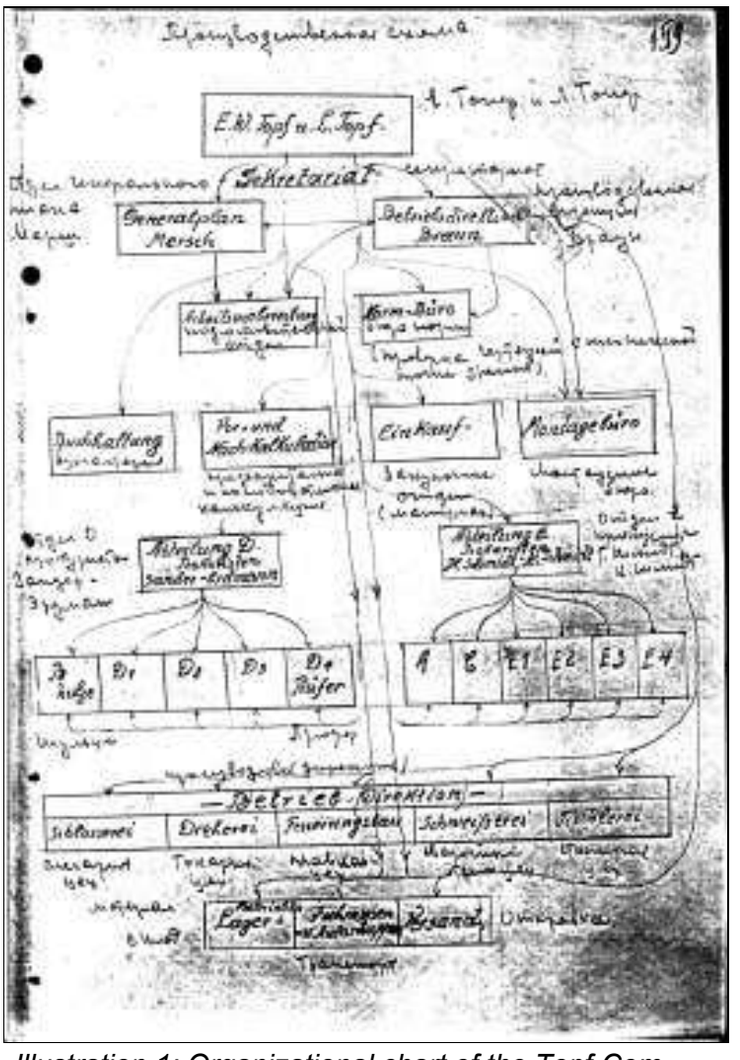

Illustration 1: Organizational chart of the Topf Company drawn by Kurt Prüfer while in Soviet captivity

- Ernst Wolfgang and Ludwig Topf, proprietors of the company
- administration office
- general planning, under the direction of Heinrich Mersch, and operations management, with Gustav Braun as head
- project preparation and standards office
- accounting, preliminary and final cost calculation, purchases and assembly office
- Department D – proxies: Fritz Sander and Paul Erdmann, with Subdepartments B (headed by Karl Schultz[e]), DI, DII, DIII, DIV (headed by Kurt Prüfer)
- Department E – proxies: Hermann and Kurt Schmidt, with Subdepartments A, C, EI, EII, EIII, EIV
- locksmith shop, lathe shop, furnace shop, welding shop, carpentry shop
- materials warehouse, motor pool and garage, shipping

Prüfer's explanations of the company structure, which he set down during his Soviet imprisonment, are to be found in Prüfer's criminal file compiled by the Soviets as a typewritten transcript peppered with errors and lacking umlauts, probably prepared by the Soviets on the basis of a handwritten text by Prüfer. It reads as follows:[91]

> *"Mr. TOPF, Ludwig and Ernst-Wolfgang were the owners and bosses of the company and managed it directly.*
> *Both gentlemen were in charge of selecting the orders to be produced by the company in the factory.*
> *From here it was decided which orders should be accepted and which should be rejected.*
> *The directly subordinate secretariat, staffed by two ladies, passed on the instructions of Mr. TOPF to the individual departments, and it was here that the incom-*

[90] FSBRF, N-19262, Criminal Case 1719, p. 159.
[91] *Ibid.*., pp. 160-162.

ing and outgoing mail was handled and the personnel matters of the employees were processed.
The General Plan Office examined the orders received, together with TOPF, on acceptance or rejection and, if accepted, assigned a level of priority. It was also here that the control tokens or bills were received and forwarded. This office was the most important in the company and was headed by Mr. MERSCH.
The plant director, as head of the entire plant (with the exception of the technical offices), had to supervise the handling of orders within the factory, and help determine which orders were urgent and which were unsuitable for the plant and had to be rejected. In addition, it was from here that the work was distributed to the individual operating units, and the method of production was discussed and determined. Workers were also accepted [hired] *and dismissed here.*
In the project preparation office, the machine parts to be manufactured were broken down into the individual operations, the costs for machining the parts were determined, i.e. the piecework wages were set, the parts lists and the shop drawings were checked and errors corrected, and it was checked which machine parts in stock were to be used.
This office reported directly to the plant director (BRAUN).
The standards office checked all drawings and parts lists prepared for the workshop for 'standard' and correctness, and especially for the correctness of the dimensions. This office was also under the direction of the plant director.
In the accounting department, all incoming and outgoing orders were entered into the books, and invoices were prepared.
The pre- and post-calculation checked the cost estimates and, after processing the individual machine parts, calculated the expenses and also the costs of manufacturing the machines, in order to finally determine the total costs and consequently the profit or loss.
This office was under the direction of Mr. TOPF.
In the assembly office, the assemblers for [the] *individual construction sites were dispatched, and the assembly wages were determined and settled, the travel prices were prepared and the assembly duration was determined. In addition, the hand tools for the construction sites were assembled and sent off. This office was under the command of Director BRAUN.*
The department head management (D) – headed by the directors and senior engineers SANDER and ERDMANN – supervised the individual Departments B-D_1-D_2-D_3-D_4, distributed the incoming mail handed over by Mr. TOPF, and consequently assigned the technical office work, checked the drawings and factory parts lists for correctness, and supervised the outgoing mail.
Department (D) handled steam-boiler hearths, bricking-in of boilers, boilers, aeration and deaeration systems, and furnaces of all designs, garbage and waste-incineration furnaces, industrial furnaces, cable incinerators and cremation furnaces, and factory chimneys
Department Management E, – management by authorized signatories Hermann SCHMIDT and Kurt SCHMIDT, supervised the individual Departments A-C-E_1-E_2-E_3-E_4. This department processed brewery machinery and all machines necessary for malt production. Steel silos for grains of all kinds, whole malting plants and grain-drying plants. Both Departments (D and E) were under Mr. TOPF.

The plant, which consisted of a locksmith's shop, a lathe shop, a furnace shop, a welding shop, and a carpentry, employed about 650 workers, and here, by means of the existing machines, all the parts for the complete devices manufactured by the company and described above were made.
The raw iron and non-fabricated iron parts were stored in the materials warehouse and distributed according to need.
The sub-departments of transportation and shipping handled the machines finished for shipment in the factory.
The plant was under the direct supervision of Mr. TOPF and Director BRAUN."

The organizational chart of the Topf Company dated February 22, 1943, however, shows a much-more-complex structure. The main departments, which were subdivided into numerous subdepartments, were thus as follows (reproduced in Schüle 2011, p. 167):

– Operations management with the two Topf brothers as bosses, including management and general administration
– commercial departments
– technical administration
– technical departments
– the operating department, including the plant production schedule, headed by Gustav Braun, the project-preparation department, and the plant floor;
– the assembly department

In 1940, the Topf Company reached its highest number of employees: 1,064 persons, of whom 766 were blue-collar workers and 298 white-collar employees (*ibid*., p. 78). After the beginning of the Second World War, foreign workers, prisoners of war and civilians were conscripted to the Topf Company. At the end of 1942, 270 of these conscripted workers worked for Topf, and in 1943 there were already 341 (*ibid*., p. 76). On December 31, 1943, the company had 840 employees.[92] From an "employee report" of January 31, 1944, it appears that the Topf Company had 830 employees at that time, of whom 726 were men and 104 women, including 157 salaried employees and 198 skilled workers.

After the war, the Topf Company started its activities for the Soviet Office for War Reparations and Supplies of the Soviet Administration in Germany. In October 1945, it erected a waste-incineration furnace in Arnstadt.[93] An order dated February 19, 1946 for a "Cartox[94] fumigation device for 5,000-ton storage" was completed on May 30, 1948 with the site-acceptance test of the plant.[95]

In April 1948, the company was still called J.A. Topf & Sons, but was now a nationalized company with the "State Owner" Max Machemehl, the plant manager Herbert Bartels and Friedrich Schiller as head of the employee organiza-

tion. Günter Mann was entrusted with the construction of cremation furnaces under the direction of engineer Hans Streichardt.[96]

During the same year, the company was renamed Nagema Topfwerke Erfurt VEB, and the construction of cremation furnaces was relocated to Zwickau. In 1957, the company changed its name to "VEB Erfurter Mälzerei- und Speicherbau" (EMS) and was privatized in 1993 as "Erfurter Mälzerei- und Speicherbau GmbH" (EMS).

In 1951, Ernst Wolfgang Topf moved to Wiesbaden, where he reestablished the company J.A. Topf und Söhne, but it was dissolved in 1963.

Kurt Prüfer was arrested by U.S. intelligence agents on May 30, 1945, but was released on June 13. Ludwig Topf committed suicide on May 31. On July 3, U.S. occupation forces withdrew from Erfurt and were replaced by Soviet troops.

In early March 1946, Prüfer, Schultze, Sander and Braun were arrested by the Soviets. The arrest warrant was issued on March 6 by the head of the Smersh counterintelligence service,[97] Colonel Zagorul'onii, and by the military prosecutor, Colonel Žmirov of the VIII[a] Guard Army. The four engineers were suspected of crimes as stipulated in the first part of the Decree of the Supreme Soviet of the USSR of April 19, 1943 concerning "punitive measures for German-fascist criminals guilty of murder and torture of Soviet civilians and prisoners of war, for spies, traitors to the fatherland among Soviet citizens and their accomplices."

The accused were subjected to a total of 36 interrogations, 20 of which took place in Berlin between March 4 and 28, 1946, and 16 in Moscow between February 11 and March 11, 1948.

On March 28, 1946, Smersh Captain Kazantsev signed for Sander, by then deceased, an "order to cease prosecution due to the death of the accused."

On March 15, 1948, Criminal Case No. 1719 against the remaining three engineers of the Topf Company was closed with a motion for conviction signed by three senior officers of the State Security Service. On April 3, an "Order to send them to a special camp of the Ministry of the Interior" was issued against the three engineers, sentencing them to 25 years in prison.[98]

Prüfer died in Soviet captivity on October 24, 1952. Schultze and Braun were released on the basis of a decree issued by the Presidium of the Supreme Soviet on September 28, 1955 as part of an amnesty.

On June 30, 1992, the Prosecutor's Office of the Russian Federation decided not to rehabilitate the three convicted engineers. (For details see Mattogno 2014).

2. The Topf Cremation Furnaces for Civilian Use

2.1. The Cremation Furnace with a Coke-Fed Gasifier

The first cremation furnace with a coke-fed gasifier built by the Topf Co., while retaining the essential features of existing furnaces, introduced a number of innovations based on prior ideas, but in a novel configuration. In particular, the Topf furnace had an external heat source for the muffle (per Max Kergel's patent of 4 October 1908) controlled by a damper made of refractory material and located in front of the gasifier outlet (following an idea incorporated into the Knös Furnace). This damper, by keeping the combustion gases from entering the muffle, ensured a completely indirect cremation. With this furnace, Topf aimed for a front-rank position in the field of totally indirect cremation, which explains its objection to the decree issued by the Prussian ministry of the interior on 24 October 1924.

The structure and operation of this type of furnace were described at the time in the expert literature as follows (Reichenwallner 1926, pp. 28f.; cf. Document 133):

> *"The cremation furnace consists of a coke-fed gasifier, a cremation chamber (muffle), closed onto itself, of the system of channels (recuperator) located below which serves to preheat the combustion air, and of the duct taking the gases around the muffle.*
>
> *When a cold furnace is to be heated up, a small fire of wood is lit in the gasifier and is switched over to coke step by step. The gases produced by the coke or the wood move upwards and into the muffle, passing through the gasifier outlet. They then flow through the recuperator and into the flue duct of the chimney, transferring the heat they contain to the walls of the recuperator along the way; the latter are made of refractory material. In this manner, the furnace is heated to incandescence (1,000°C). The necessary gas mixture is produced with a supply of air.*
>
> *At this point (1,000°C) the furnace is ready for the cremation. The damper at the outlet of the gasifier is closed in such a way that the gases flow through the channel surrounding the muffle, maintaining the latter at incandescence from the outside. Thus the gases can no longer enter the muffle. The front introduction door of the muffle is opened and the coffin is introduced by means of the introduction cart; in this way the coffin is deposited on the cremation grate and the cart is immediately withdrawn from the muffle. The front opening as well as its outside cover are closed immediately. The necessary combustion air – which flows into the cremation chamber at a high temperature and incinerates the corpse – enters the series of channels below through the open dampers, rises through the channels in a direction opposite to that of the discharge gases up to the highest point of the vault above the muffle and there enters the muffle at a high temperature.*
>
> *Just before it leaves the muffle, the saturated combustion air is diluted with preheated air; an operation without smoke or odor is obtained in this manner. The duration of a cremation is 60-75 minutes, depending on the size of the corpse.*

The entire cremation process can be observed by the operator through viewing glasses in front and rear. The furnace combines the two corpse-cremation systems, i.e. direct and indirect cremation. Furthermore, the most-modern conceptual and technical elements have been incorporated. The advantages of the furnace are ease of use and control, minimal fuel requirements, very-rapid cremation, odorless and smokeless operation.

The design of the furnace is very solid. Between the inner wall of refractory material and the outer brick wall, there is a thick layer of rock wool which brings loss by radiation down to a minimum. The furnace consists of massive, top-quality refractory clay which not only makes for a stable structure but also serves to accumulate heat. This system design aims for a long life of the furnace. The outer brickwork is built in an arch-like way, as a vault, and held together by steel bars, angled or in T-shapes; the latter are linked by solid bolts.

The ashes are cooled near the front of the lower section of the furnace in an ash container with a smoke-extraction fan, and is then transferred to the urn.

The cremation process as such takes place out of sight of the bereaved. The coffin, set up in a dignified manner in the chapel, is lowered slowly and silently to the sound of a solemn piece of music and is then introduced into the cremation chamber by means of a cart of appropriate design. The remains of the ash, purely white, are collected in the ash container and can then be buried or placed in a columbarium."

Topf had become a major competitor also in the fields of design and construction of cremation furnaces by the early 1920s. At that time, its most-resounding success was undoubtedly the erection of two cremation furnaces in Moscow in 1926. A publicity leaflet of the same year, entitled "Furnaces for crematoria, Topf system" informs us about the activities and developments of the company (Topf 1926; cf. Document 134):

"The 'Topf' Furnace for crematoria is the result of nearly fifty years of experience in the field of technical combustion equipment and is suitable for both direct and indirect cremation.

The furnace consists of the coke gasifier with its routing of the carbon-monoxide gases, the independent cremation chamber (muffle) and the channel system beneath (recuperator) which is used for preheating the air needed for the cremation. The preheated air thusly produced does not enter into contact with the spent gases, because the air channels are totally isolated from the flue-gas channels, so that, in the case of indirect cremation, the cremation takes place with pure atmospheric air which is heated up to the required temperature only on its way to the muffle.

Between the internal and the external brickwork, over the whole length and height of the furnace, is laid a thick layer of insulation made of bricks of diatomaceous earth; in this way the thermal radiation is reduced to a minimum. In the design of our most-recent model we have made use of our extensive knowledge in the domain of heat economy applicable in this field with this particular idea in mind. The ensuing advantages show up most clearly when the furnace is not in daily use. The insulating layer of diatomaceous earth retains the heat over a long period, and the amount of heat required for a new incinera-

tion series is correspondingly less. Moreover, the time needed for preheating is considerably shortened.
The external brickwork is designed in accordance with the Topf Arch System of proven effectiveness; it ensures that the brickwork in the shape of an upright vault is wedged between robust steel beams, both angular and I-shaped. This system of construction guarantees a long service life and prevents the formation of cracks, which would otherwise develop quite easily because of the high temperatures. The fittings are made from refractory castings.
In recent years, we have erected a series of cremation installations attached to existing benediction chapels or similar halls. In most cases, such an arrangement obviates the need for a lowering device and now enables all those municipalities that had to reject the idea of building their own crematorium again and again for financial reasons, to acquire a cremation installation at a rather moderate cost. Along these lines, the crematoria at Erfurt, Grünberg, Guben, Höchst a.M., Ilmenau, Magdeburg, and Suhl came into being.
Lately we have added air heaters which make use of the spent gases; these devices are incorporated into the flue duct just upstream of the chimney. They consist of a heat exchanger with a large number of so-called bags in which the spent gases and the air circulate separately: a blower mounted in front draws in fresh air and pushes it through the air bags. The spent gases are led through adjacent bags; in this manner the air warms up and can be taken through ducts into the chapel to heat the latter. Such an arrangement makes the installation of a central heating system superfluous. Leaving aside the fact that the capital outlay is far-lower than for a separate boiler for central heating, the small blower has such low operating costs that heating is essentially free of cost.
Crematoria with furnaces and Topf mechanical systems under construction in 1926 are located at

Wilhelmshaven	*1 furnace*
Giessen	*1 furnace*
Moscow	*2 furnaces*

Since 1922 we have thus built or received orders for 28 furnaces, an achievement so-far-unsurpassed.
Figures 8 and 9 show the church of the Donskoye Cemetery in Moscow where 2 furnaces are presently being built by us.

***

The City Director *Arnstadt, 10 February 1925*
Arnstadt in Thuringia
Dept. IV

[To:] *J.A. Topf & Söhne Co., Erfurt*

The cremation furnace installed by Topf & Söhne Co., Erfurt, was handed over and started up on 1 October 1924. Up to now, 57 cremations have been carried out. Cremations take place irregularly, which leads to uneven periods of preheating and coke consumption for the individual cremations. Gas coke is being used as fuel. Preheating the furnace requires 2-2 ½ hours.
From the beginning of preheating up to incandescence and complete combustion, coke consumption has been as follows:

for the cremation of one corpse *169-260 kg* } *incl.*
" " " of two corpses on one day *234-314 kg* } *preheating*

The cremations take place without generation of smoke or odor over a period of ¾ to 1 ¼ hours for each corpse. The chimney, 18.0 m high and erected by J.A. Topf & Söhne Co., functions satisfactorily. The same applies to the [coffin-] *lowering mechanism, likewise supplied by the company.*
In connection with the channel for the gas flow from the cremation furnace to the chimney, J.A. Topf & Söhne Co. have installed an air-heating device for heating the cemetery chapel. The air temperature at the exit points in the chapel is 50°C on average. In the case of cremations, the chapel can thus be heated quickly and without any additional fuel.

The cemetery department.
Signed: signature

* * *

City of Erfurt *Erfurt, 25 June 1925*
Department of Gardens and Cemeteries

[To:] *J.A. Topf & Söhne Co., Erfurt*

The cremation installation with two furnaces erected by J.A. Topf & Söhne Co. went into operation on 11 April 1923. Up to date, 700 cremations have been carried out.
Over the two years of operation of the furnaces, no failures have occurred up to now.
The special design of the furnaces and the good insulation have led to very low temperature variations, which is also very beneficial for the durability of the brickwork. We must underline the exceptionally simple control of the furnaces.
Unfortunately the cremation furnaces are not yet in daily operation. Therefore, the determination of the fuel requirements per corpse cannot yet be fully assured.
Using gas coke as fuel, for the period starting with preheating up to incandescence, complete incineration, and removal of ash remains, our records permit us to report the consumption as follows:

1. for the incineration of	*1 corpse in one day*	*3¼*	*hwt. of gas coke*
2. "	*2 corpses in succession*	*5*	*"*
3. "	*3 "*	*7¼*	*"*
4. "	*4 "*	*9*	*"*
5. "	*5 "*	*10¼*	*"*
6. "	*6 "*	*10½*	*"*
7. "	*7 "*	*10½*	*"*

The design of the Topf System allows the cremations to be executed completely without any smoke and odor.
The maximum duration of a cremation amounts to 1¼ hours.
The Municipal Department of gardens and cemeteries

Signed: signature

* * *

The Director of the *Weimar, 30 May 1925*
Land Capital (Buildings Department)

[To:] *J.A. Topf & Söhne Co., Erfurt*

In reply to your request of the 22nd of this month we inform you that the cremation furnace installed by you in this crematorium has operated successfully up to now. In order to bring about a more economical operation, cremations are carried out only on Tuesdays and Fridays. Preheating requires 2-3 hours, a cremation lasts 1-1½ hours. Each of the latest 24 cremations required on average 2.7 hl [hektoliters] *of gas coke (incl. preheating).*
The Deputy Mayor

Administration of *Halle upon Saale, 7 October 1924*
Gertrauden Cemetery

[To:] *J.A. Topf & Söhne Co., Erfurt*

In reply to your letter of 3 inst. we are pleased to inform you that the cremation furnaces erected by you in 1915 have been operating so far to our complete satisfaction. The installation was started up on 15.12.1915, and altogether 2,670 corpses have so far been cremated in the two furnaces. In order to reach a temperature of 1,000-1,100°C with a cold furnace, we require some 3½ to 4 hwt. of metallurgical coke, whereas only 1 hwt. of this fuel is needed with a furnace already in operation. The duration of a cremation depends upon the size and nature of the deceased and amounts to ¾-1¼ hours at this plant.

Municipal Operations Dept. *Hanover, 10 October 1924*
Heating and Machinery Section

[To:] *J.A. Topf & Söhne Co., Erfurt*

In reply to your letter of 3 inst. we can inform you that the operation of our crematorium has not yet reached a level allowing us to establish a certificate concerning the furnaces. For the time being, we can only confirm that we are satisfied with the furnaces supplied and have not yet noticed any substantial wear after the 300 cremations carried out so far. As a consequence of low and infrequent usage, at the present time, we require some 100 kg of metallurgical coke for each cremation. We hope that, with the completion of the whole plant, usage of the furnaces will intensify leading to a lower fuel requirement.
In any case, we are satisfied with the furnaces to such a degree that we have always replied in a positive way to the various inquiries addressed to us.

The Municipal Directorate *Ilmenau in Thuringia, 2 August 1924*
Municipal Building Department

[To:] *J.A. Topf & Söhne Co., Erfurt*

As requested, we are pleased to confirm that we are satisfied with the furnace plant erected by you in our crematorium. The installation has functioned very well with respect to the directions concerning the cremation of corpses and from

the point of view of fuel economy. When properly operated, the furnace has so far not led to any odor nuisance in the vicinity. In spite of the sometimes intensive use of the furnace, no wear or tear has been noticed so far.

Association for Cremation (reg. ass.) *Suhl, 20 October 1923*
Suhl

[To:] *J.A. Topf & Söhne Co., Erfurt*

We are happy to inform you that, technically speaking, we are satisfied with the installation erected by you in our crematorium. The furnace works well and has relatively low coke requirements. The operation of the draft enhancer is excellent and the chimney, as linked to it, works particularly well. Overall, the execution of the work involved has been most-exact.

The City Council at *Hirschberg, 26 May 1923*
Hirschberg in Silesia

[To:] *J.A. Topf & Söhne Co., Erfurt*

In reply to your letter of 19 inst. we confirm that the cremation furnace supplied by you in 1914 works satisfactorily.
Operation is easy and simple. The design has turned out well. As far as the installation is concerned, no deficiencies have been noticed so far.
The following amounts of coke are needed:

for the first incineration		*5*	*hwt.*
"	*" second*	*"*	*3 "*
"	*" third*	*"*	*1 "*
"	*" fourth*	*"*	*– "*

The duration of a cremationis about 1½ hours. Preheating takes 2-3 hours. For a single preheating operation, the generator damper is closed. However, as additional feeds are required for each succeeding cremation, the generator damper must be opened [again].

2.2. The Gas-Fired Cremation Furnace

The gas-fired furnace mentioned by Sander in his letter of 14 April 1936 is the "High-performance furnace with rotatable ash-grate, D.R.P. (Deutsches Reichspatent)" model 1934. The operation is still an indirect one, using hot air from metal tubes located above the muffle. The post-combustion chamber is equipped with a rotatable grate in accordance with the patent granted to Viktor Quehl on 17 October 1932 and taken over by Topf on 17 May 1934 (cf. following chapter). The furnace appears more-elaborate and considerably more-voluminous than the Volckmann-Ludwig Furnace: it still has the two-level design of the coke-fired furnace, with a total height of some 5 meters; the controls for rotating the grate and the ash-removal device are located on the lower level. Even

the section located in the furnace hall, measuring 3.70 by 2.60 m, is far-more-voluminous than the Volckmann-Ludwig Furnace (3.10 by 1.70 m).

Two furnaces of this type were set up in the Cologne Crematorium. A contemporary article describes the design and operation in the following words (Etzbach 1935, pp. 3-5):

> *"As the furnace is heated each day in the early morning by means of a gas burner and is at incandescence (around 1000°C) after one hour of preheating, the coffin is set alight right after its introduction into the furnace, because wood immediately catches fire at that temperature. Of course, the gas burners are closed first, so that the corpse is now being cremated by means of air at a high temperature, and after approximately one hour only pure ash from the bones remains (about 2 liters).*
>
> *The generation of the high-temperature air is effected by a metallic air heater, which is located within the furnace and is fed by a blower located outside. On their way to the chimney, the discharge gases from the furnace must pass through this heater and heat it to the point where its tubes begin to glow. In this way, a noticeably shorter cremation time is achieved. Moreover, with high-temperature air, smoke can be prevented, which would otherwise not be the case, if heavily varnished coffins or similar are used.*
>
> *The cremation furnace* [Document 135] *consists of the cremation chamber (a) with the tiltable plates of the grate (b) below and with the ash chamber and its ash grate (c) located underneath it. The movable burner for low-pressure gas (d) is situated in the front part of the furnace on the inside. The cremation itself may be viewed through an observation device (e). The tubes of the air heater are located above the cremation chamber.*
>
> *Once the corpse has decomposed under the effect of atmospheric air at high temperature, the ash (bone residue consisting of calcium phosphate and iron oxide) falls through the refractory blocks of the grate onto plates of cast-iron Pyrodur (b) under the effect of gravity. These rotatable plates are turned from the outside of the furnace and remain in a vertical position. In that way, the ash falls onto the ash grate (c). This grate, too, can be tilted and is controlled from outside the furnace. Below this grate is the ash receptacle. If the grate is tilted 90°, the ash falls into the receptacle beneath. After a suitable cooling period, the ash is transferred into a (metallic) urn of some 15 cm in diameter and a height of 20 cm; here, for reasons of reverence, suitable tools are used in order to avoid any contact between the ash and* [human] *hands. The urn is then closed and marked with the name and the necessary data to be held in the chapel hall or taken to another location which possesses the required characteristics of reverence.*
>
> *We must also stress in particular that, before a coffin is introduced into the furnace, a control token made of refractory material (Schamottemarke) is attached to it, showing the serial number under which the coffin has been registered in the list of the crematorium administration. This refractory token, which is fireproof, accompanies the entire process and ends up with the ash; it is removed and attached to the lid of the urn."*

The next type of furnace (Document 136) shows technical improvements in the tube system of the air heater and in the ash-extraction system, aside from the incorporation of a second, smaller burner into the post-combustion chamber. The

engineer Fritz Schumacher describes it as follows (Schumacher 1939, pp. 25-27):

"The Topf Furnace has an outer brick casing with clinker or brick facing. A strong reinforcing framework of T, U, or angle bars made of wrought iron holds the enclosure together. The visible outside surfaces of the furnace possess an arch-like brickwork in order to prevent the formation of cracks.

The inside of the furnace is made of highly suitable fireclay material, and between it and the enclosure is located a continuous layer of insulation made from bricks of diatomaceous earth and rock wool.

Within the furnace we have the cremation chamber with lateral discharge of the gases and the gas-discharge channels situated on the right and on the left side, the cremation grate, the tiltable ash grate below, and the post-combustion chamber with the ash-extraction grate.

To the right and left of the cremation chamber there are the tubes of the air heater providing high-temperature air. Whereas the upper four heating coils are made from Sikromal Steel, which withstands temperatures up to 1200°C, wrought-iron tubes with especially thick walls are used for the lower portion. A blower located outside and guaranteed to run silently feeds air to the two tube systems. In order to ensure that the tube systems on both sides are fed equal amounts of discharge gas, there are refractory baffles which direct the discharge. These refractory baffles, arranged horizontally, also serve to store heat.

On the inside of the front is a low-pressure gas burner rated at 30 m³ per hour. This burner is movable.

As the Reich legislation on crematoria allows the use of fuel during the cremation only in particularly difficult cases, the Topf Furnace, in order to respond to the wishes of the legislature, is provided from the outset with a burner in such a way that, once the furnace has reached its operating temperature, it can be retracted, and a cast-iron flap next to the burner seals its opening. Above the post-combustion grate is another small burner, rated at about 5 m³ per hour, which is used only in special cases.

For closing the cremation chamber a muffle-closing device is used consisting of two parts and made of cast iron, lined with fireclay, which rests on the framework of the furnace. Immediately in front of this closure is an insulating plate consisting of two sections made of a double layer of asbestos held by a frame of wrought iron to prevent heat losses to the outside.

Both above the tiltable ash grate and within the cremation grate there are outlets for the hot air needed for the combustion. A further hot-air outlet is provided over the ash-extraction grate.

The tiltable ash grate is designed to be operated from the outside. This grate has a highly refractory Pyrodur frame, and the interstices are filled with monolite clay. Another closure in the flue channel completely closes the furnace against the chimney.

The ash box has two pairs of wheels for easy moving. The hot-air-closing devices are located in the front portion of the furnace above the main burner. They are labeled: muffle – post-combustion – tiltable ash grate – ash extraction.

The controls of the flue-duct damper are also located next to those of the hot air.

The discharge gases pass through the furnace along the following route:

From the gas burner they move to the underside of the refractory grate where they heat up the tiltable ash grate, and from there they flow on into the cremation chamber through the blocks of the grate. After having passed through the chamber, they pass into the openings in the vault of the muffle, strike the muffle laterally and drop down through the lateral discharge channels. They leave the channels here on both sides, cover the post-combustion grate, come together behind it, only to split up again when entering two side channels running along the cremation grate, from where they move into the flue duct.

Thanks to this gas routing, the mass of refractory brick heats up uniformly inside and out; in this way a longer service life of the refractories is guaranteed. The heat content of the gases is, moreover, made good use of, and the gases leave the chimney with little smoke and odor.

Thanks to the tiltable grate, no stoking tools are needed in the Topf Furnace in order to remove the ashes of the corpse."

On 24 June 1950 Martin Klettner, an engineer working for the Topf Co. which had moved to Wiesbaden after the war,[99] patented a new type of cremation furnace which will be described in Chapter 3. The furnace had already been built at Wiesbaden prior to the issuance of the patent, as we can see from the following letter written by the Wiesbaden city authorities on 19 December 1949 (see Document 137):

"We confirm herewith that Senior Engineer Martin Klettner has executed the intended reconstruction of the cremation furnace over a period of 2½ weeks and has incorporated improvements based on your experience.

Mr. Klettner has demonstrated the operation of the furnace and has handed it over after a test run extending over three days and involving a total of 16 cremations to our complete satisfaction.

The performance of the furnace surpassed all expectations, especially with respect to the fuel consumption. As early as the third day, cremation times of 40 minutes were attained without any fuel consumption except for preheating.

You are at liberty to show the furnace to interested parties after giving us sufficient notice.

Any publication of this letter without our prior approval is not permitted."

Klettner had probably only revised a plan and a "provisional construction drawing" of the furnace that the Topf Company of Erfurt, which had been nationalized by communist East Germany in the meantime, claimed for itself in a letter dated April 6, 1948.[100]

In 1989 two gas-fired Topf furnaces were still in operation at the crematorium of the Dortmund Central Cemetery. They had obviously been modernized with respect to automation and had been equipped with technical control devices.

We will now describe the operation of these installations: Cremation takes place at two levels: the main cremation takes place on the upper floor. After the introduction of the coffin into the muffle, the cremation residues drop into the

---

[99] Ernst Wolfgang Topf, one of the two brothers who owned the company of the same name (the other, Ludwig, had committed suicide on May 30, 1945), moved to Wiesbaden in 1951, where he re-established the J.A. Topf und Söhne Company, which was dissolved in 1963, however. M. Klettner's patent bears the heading "J.A. Topf & Söhne, Wiesbaden" because it was issued on January 5, 1953.

[100] "An die Stadtkommandantur, Oberlt. Proskurin, 6.4.48." SE, 5/411 A 100. See Document 138.

post-combustion chamber beneath when the grate is tipped, where they burn out completely. In the meantime, another coffin is introduced into the muffle above. The ash is removed when the post-combustion is complete.

Before introducing coffins successively into the muffle, they are given an identification token made of refractory clay, bearing a serial number, which remains with the corpse and the ash over the whole duration of the cremation and allows identifying the decedant when the ash is extracted.

The time required for the cremation varies between one-and-a-quarter and one-and-three-quarters hours, depending on the nature of the corpse. In a normal shift of eight hours, five corpses per furnace are usually cremated. In early 1989, because of the great number of corpses awaiting cremation, double shifts were arranged, with 10 corpses, sometimes up to 12, being cremated within a day, with a consumption of some 21 m³ of gas per cremation. Later on, after air- and gas-flow controls were added, consumption went down to less than 17 cubic meters.[101]

2.3. The Cremation Furnace with Electrical Heating

Topf built the first electrically fired German cremation furnace; it was set up at the Erfurt Crematorium in 1933. Like the gas-fired furnace, this device, too, had two levels. The 1934 model mentioned in the preceding subchapter had a basic design which was suitable for both gas firing and electrical firing (Documents 140f.).

The new design is explained in an article which summarizes the patent application filed by Topf ("Elektrisch…" 1935, pp. 89f.; cf. Document 139):

> *"The electrically heated Topf Furnace installed at the Erfurt Crematorium consists of a cremation chamber which is heated on both sides by 6 heating coils made of nickel-chromium alloy, through which passes an electric current and which are placed in the recesses of specially shaped bricks. The heating coils are protected from the direct effect of the flames which develop during the combustion of the coffin by stainless-steel plates placed in front of them.*
> *These 12 coils have an output of 40 kW. The muffle is closed by a door and by a panel made of fireclay.*
> *The grate is cross-shaped and has also two heating coils with an output of 12 kW.*
> *Underneath the grate is the inclined plane for the ash made of specially shaped refractory bricks which, again, contain 4 heating coils having a total output of 18 kW.*
> *The inclined plane ends at a closure plate below which the post-combustion chamber is located with its 7-kW heating coil. The floor of the post-combustion chamber consists of a perforated plate. Beneath it is the ash receptacle. The heating coils of the Topf Furnace at Erfurt have a total power output of 95 kW.*
> *In the flue-gas channels of the cremation chamber, Aeroterm*[102] *tubes arranged along a slope are installed. They are fed by means of a blower located on the*

[101] Letters of *Grünflächenamt* (public parks department) of the City of Dortmund to the author dated 18 January and 24 February 1989.

[102] Aeroterm tubes "consist essentially of a battery of finned tubes and a helical blower inside a metal

outside of the furnace. The air which is heated in these tubes to a high temperature enters the cremation chamber below the refractory grate through two channels, each of which has four openings. Before striking the corpse, the air flows past the glowing mass of refractory clay. These air outlets are not mere nozzles; their dimensions are 70 by 100 mm.

Above the cremation chamber is the discharge outlet for the gases, which can be closed. The spent gases leave the cremation chamber at the top, strike its upper portion, and are then led downwards by means of two channels on the sides of the cremation chamber, passing through the lower portion of the inclined plane towards the flue-gas channels and from there into the chimney.

The operation of the furnace is very simple. The heating coils are switched on and off by means of a remote-control switch. All the controls are grouped in a box which can be placed next to the introduction door. In order to benefit from cheaper night-rate electricity, the furnace is switched on automatically by a timer; thus, attendance is required only, and in a limited way, when the coffin is introduced. Heating is controlled by a device which shuts off the furnace when the temperature has reached any desired level, so as to avoid any wastage of electrical power."

Quite soon, however, this furnace would exhibit serious operational problems, especially the generation of smoke during cremations. Exacting investigations by the administration of the Erfurt Crematorium showed that, with a draft of 12 to 24 mm of water, the velocity of the spent gases was so high that they did not have sufficient time to burn out within the muffle and cooled down to a level below their ignition temperature as soon as they entered the flue duct. The administration of the crematorium was therefore obliged to carry out technical modifications of the plant: a combustion chamber (*Brennkammer*) was installed above the muffle in an effort to bring down the gas velocity, and the damper at that point was removed; the cross-section of the channels for the combustion air were enlarged, and two new channels were added which brought air into the muffle through two openings in its upper part. The flat supporting beam for the coffin was replaced by a corrugated beam.

In 1934 Topf designed, moreover, a cremation furnace which could operate with either gas or electricity. Document 140, consequently entitled "Topf Cremation Furnace 1934 (For gas and electrical heating)," shows the installation from the outside. Document 141, "Topf Cremation Furnace 1934," illustrates its design. Following the example provided by the Volckmann-Ludwig Furnace, it had an outer metal facing (*Blechummantelung*), which provided it with a very-modern appearance. The incineration chamber (*Einäscherungsraum*) was closed by means of a sliding door, mounted obliquely; a decorative door (*Prunktür*) was mounted in front of it. The opposing part sported a viewing port (*Schauluke*). Each of the side walls had three openings for the spent gases. The coffin rested on three corrugated refractory beams. Below it was located the tiltable

---

container with baffles which allow steering the flow of hot air. The heat exchange takes place in forced convection with a high thermal efficiency (1,500 – 3,000 kcal/m² hr), and is highly adaptable depending upon the design. The air velocity is higher than what would normally be agreeable (0.20 – 0.40 m/sec) and the noise level is high (50-60 dbA); hence, in view of the high output, their usage is primarily in industrial and large-scale installations." *Manuale…* 1990, p. E 589.

grate for the collection of the ash (*drehbare Asche-Sammelplatte*) with the ash post-combustion chamber (*Nachverbrennungskammer*) below; its tiltable grate permitted the transfer of the ash to the receptacle underneath and its removal through a suitable opening (*Ascheentnahme*).

In the front part of the furnace, but on the lower level, there was a blower (*Druckluftgebläse*) feeding air through a double coil of tubes acting as an air heater (*Röhren-Luft-Erhitzer*); the air from these tubes passed through the six vertical flue-gas ducts, located on both sides of the cremation chamber, where the flue gases transferred their heat content. The combustion air heated in this way flowed through eight openings below the coffin, passed between the refractory beams, continued through another eight openings above and below the tiltable plate, and then entered the post-combustion chamber. A chamber with dampers was placed above the cremation chamber in order to reduce the velocity of the fuel gases.

When these changes had been carried out, test cremations were undertaken at the Erfurt Crematorium. The chart published by engineer Konrad Weiss (Document 142) refers to five cremations which took place on 17 and 18 April 1934. The duration of the individual cremations was as follows:

First cremation	about	1 hr 45 min.
Second	″	2 hr
Third	″	1 hr 40 min.
Fourth	″	1 hr 50 min.
Fifth	″	1 hr 30 min.

The temperature recorded at the center of the muffle was higher than that in the rear portion and varied between 850 and 950°C. The temperature of the inclined plane was always below 600°C (Weiss 1934, pp. 453-457).

A total of 1,622 cremations were carried out in this furnace before it was dismantled and replaced by a more-modern model set up in the Erfurt Crematorium in 1936. Compared to the former, this model (Documents 143-145) presented numerous technical improvements. The vault of the muffle is closed, and both the additional combustion chamber and the channel for the spent gases are absent. The lateral walls of the muffle, below the onset of the semicircular vault, are strongly inclined and extend below the grate as inclined planes for the ash; they reach down to a previously non-existent tiltable grate. Below the latter is an electrically heated and retractable post-combustion grate. The supporting grate for the coffin consists of three corrugated beams.

The spent gases leave the muffle through four square openings in each of the side walls and enter two channels which go down vertically and open up above the post-combustion grate, which they traverse downwards and then enter the flue duct. On the inside of these two vertical channels there are four horizontal metal heat-recovery tubes, 120 mm in diameter, into which a blower, located outside the furnace, feeds the combustion air which in turn enters the muffle through two openings set into each of the side walls, above the tiltable grate and below the muffle grate. Through other channels, combustion air also enters the muffle from an opening behind the last supporting beam of the grate. From there it flows also into the space below the post-combustion grate. The heating

coils are no longer contained in recesses protected by metal plates but in appropriate channels made of shaped refractory bricks.

This furnace is described by the Topf Co. in the following manner (Schumacher 1939, pp. 28, 30; cf. Weiss 1937, pp. 159-162):

"The furnace consists of an outer cladding of sheet metal which is held in place by robust T, U, and angle-shaped bars. The entire furnace is built from the most-appropriate refractory material, and between it and the outer shell there is a thick layer of diatomaceous earth bricks as well as glass-fiber and rock-wool panels.

The furnace itself consists of the cremation chamber with its flue-gas channels to the right and left, of the cremation grate with the tiltable ash grate below, of the post-combustion chamber and a grate for ash extraction. On either side of the cremation chamber, preheating tubes for the combustion air are set into the flue-gas channels, heating the air to a high temperature. Whereas the coils of the two top sections are made of Sikromal Steel, we use cast-iron tubes with particularly thick walls for the lower sections. A low-noise blower located outside the furnace feeds both sets of tubes.

For the closure of the cremation chamber there is a muffle closure which can be suspended either from the furnace framework or from the ceiling of the furnace hall. In front of this closure, there is an insulating plate made from double asbestos panels held by a wrought-iron frame.

Above the tiltable ash grate, as well as within the cremation grate, feed openings for the hot air required for the combustion have been placed. A further opening for the hot air is located above the ash-extraction grate. This grate has a rim of Pyrodur wrought iron, and the interstices are filled with compressed Monolite.

The furnace is well separated from the chimney by a draft damper. The ash receptacle has two sets of wheels for easy movement. The discharge gases take the following route:

The discharge gases leave the cremation chamber through two openings set into the right and left sides of the cremation chamber, pass through the upper channel around the horizontally arranged plate of refractory clay into the second and third channels and leave to the right and left of the combustion grate, enveloping it, then flow behind and below it through a common channel and are then led to the chimney via the flue duct.

The refractory material is heated uniformly, inside and out, by the discharge gases, guaranteeing in this fashion a longer service life of the refractory material. Furthermore, the spent gases are used up completely and leave the chimney with minimal smoke and odor. No devices are needed for the extraction of the corpse ash.

Location of the electrical equipment for cremation:

The maximum total power output is 85 kW, of which 48 kW are installed in the two side walls of the main cremation chamber (muffle), 15 kW in the chamber below the grate, 10 kW in the post-combustion and 12 kW in the air channels located on either side of the grate.

In the main cremation chamber there are 6 openings on either side, for a total of 12, which contain two electrical circuits. In this way it is possible to switch the two sides on or off separately.

The coils that are located in the rear portion of the furnace are linked by cables to the control panel, which is located on the wall of the building behind the furnace. This panel is equipped with the timers, the ignition device, the timer clock, and the pushbuttons for ignition with their control lights.
All electrical circuits have push-button controls with control lights in such a way that one can see at any time which circuit is powered.
The ignition device prevents excessive temperatures in the furnace. For this, the furnace starts and stops automatically at 700 and 900°C, respectively, as a function of the desired temperature. The furnace can moreover be switched on or off at any moment by means of the ignition control, even at times when no attendant is present.
This means that the furnace can switch on and preheat to the operating temperature automatically, even during the night, at any desired moment without manual action."

The chart for this furnace published by the engineer Konrad Weiss (Document 146) covers two consecutive cremations. The durations of the cremations turn out to be considerably shorter than in the previous furnace, between 55 and 70 minutes. This is due to the thermotechnical improvements of the second furnace, above all by the incorporation of a tiltable grate which – allowing as it did the separation of individual corpses – permitted the introduction of another corpse while the residues of the former burned out in the post-combustion chamber.

After some 3,000 cremations carried out over a period of three and a half years of operation, this furnace was worn out to the point that it had to be dismantled and rebuilt.

The new furnace (Document 147) brought along further technical improvements: the combustion air flowed from a single hole in the rear portion of the muffle, striking the coffin from below; another conduit moved air below the post-combustion grate. Furthermore, the spent gases no longer flowed through the post-combustion grate, leaving instead through two holes in the rear part of the post-combustion chamber and from there into the flue-gas channel.

Construction work on the new furnace ended on 1 December 1939, and the furnace was slowly dried until 31 January 1940 by means of 750 kg of wood. Its performance was much improved. The performance of this furnace was documented by the engineer Rudolf Jakobskötter (Document 148) on the basis of three cremations in succession. Cremation times were very short: some 65, 50 and 40 minutes respectively.

In the light of what we have stated in Chapter 4 of Unit I, it is obvious that for the cremations shown in the chart – which had the purpose of highlighting the efficiency of this furnace – combustion did not come to completion on the tiltable grate, but continued and ended in the post-combustion chamber, as it had done in the Volckmann-Ludwig Furnace at Hamburg, in which the solar plexus was burned in the post-combustion chamber.

Document 149 shows an electrically heated Topf furnace with further technical modifications, the most-important of which were the double door for the closure of the muffle, the tiltable post-combustion grate and the heat-recovery

system with its metal tubes set into a separate chamber upstream of the flue duct (Jakobskötter 1941, pp. 579-587).

3. The Topf Patents of the 1920s and 1930s

In the preceding chapters we have seen that Topf introduced a series of truly novel ideas into the technology of cremation, which made it the most-important company in Germany in that sector within a single decade. Its untiring research and development activity is also reflected in the patents directly issued to it or which it acquired over the years of its most intensive activity. All this time, however, construction of furnaces for crematoria remained a marginal activity in the plants and on the financial statements of the company, and the patents which the firm obtained clearly reflect this fact.[103]

In this chapter we will publish the text of all Topf patents relating to cremation furnaces and other combustion devices, but will translate only the most-important ones, leaving aside the two patents referring to the coffin-introduction device (24 August 1920 and 4 May 1938; Documents 150 and 154) and the patent application of 16 November 1942 concerning "Air-cooled grate plate for mechanical push grate" (Document 159), which does not concern cremation furnaces but industrial gasifiers.[104]

[103] Cf. the corresponding list shown in Appendix 1.4.

[104] The patents mentioned in this chapter derive from the *Deutsches Patentamt* in Berlin. Documents 155 & 159 are merely patent applications not indicating whether any patent was eventually granted.

The invention relates to a device for the post-combustion of residues in corpse-cremation furnaces, primarily for the purpose of burning the wood ash which is mixed with the corpse ash.[105] The object of the invention differs from known post-combustion devices in that the removable receptacle for the combustion residues, placed at the end of the inclined floor of the ash-dropping area, has a perforated bottom and is placed over the outlet of a controllable feed of combustion air. This arrangement has the advantage of being very simple. Furthermore, above the residue receptacle and below the lateral gas exhausts there is a gas-permeable slide, blocking ash from dropping into the receptacle, which enables the ash, still undergoing post-combustion in the receptacle, to be kept separate from a further cremation in the case of cremations in succession.

Fig. 1 shows the longitudinal section of the furnace in the schematic chart of an example of the realization. Fig. 2 is the front view of the post-combustion device.

At the front end of the furnace, below the ash-dropping area, there is a receptacle *a*, equipped with a perforated bottom *b* and a combustion-air supply *c* located beneath the latter. The supply can be controlled by dampers *d* or similar.

The combustion residues are moved into receptacle *a* shortly before the end of the incineration process and subjected there to a post-combustion process with the spent gases escaping through the lateral exhausts *g* of the furnace.

In order to prevent the residues of two successive cremations from reaching receptacle *a* concurrently, a retractable plate *e* is mounted above receptacle *a* which isolates the receptacle from the ash-dropping area *f.* This plate is permeable for the gases, *e.g.* by possessing small holes, in such a way that the post-combustion gases can leave, but no ash residues from ash dropping area *f* can reach receptacle *a*. Consequently, a fresh cremation may be started before the post-combustion of the residues of a previous cremation has come to an end in receptacle *a*.

Patent claims:

1. A device for the post-combustion of residues in corpse-cremation furnaces, characterized by the fact that the removable receptacle (*a*) placed at the end of the inclined floor of the ash-dropping area (*f*) has a perforated bottom (*b*) and is located above the outlet of a controllable combustion-air supply (*c, d*).

A device in accordance with Claim 1, characterized by the placement of a gas-permeable retractable plate (*e*) above the receptacle, below the lateral gas exhausts (*g*), to shield the receptacle against any ash dropping from the furnace. [Document 151]

* * *

[105] This refers to the complete combustion of the combustible substances.

3) Deutsches Reich. Published on 17 October 1930. Reich Patent Office. Description of Patent No. 561643. Class 24 d. Group I. Q 1735 V/24d

Day of publication of issuance of patent: 29 September 1932.

Cremation furnace with tiltable grates

Patented in the German Reich from 15 April 1931.

Existing cremation furnaces possess stationary furnace sections – the muffle grate and the ash grate – to support the coffin and the corpse parts to be incinerated.

These have the disadvantage that after their incineration the corpse parts have to be scraped from these surfaces by means of a scraping device. Such an intervention into the incineration process does not constitute a dignified form of cremation. Furthermore, the introduction of the scraping device into the furnace provokes a considerable loss of heat by allowing cold air to enter the furnace through the doors while they are open. The iron scrapers may also easily damage the glowing brickwork.

This invention obviates the use of scraping and stoking devices in such a way that the muffle grate which supports the coffin and the corresponding ash grate can be pivoted from the outside around one or several axes, with the grates being optionally split into several pivotable sections with an arbitrary orientation of the axes.

This makes it possible to remove totally or in part, from the outside without opening the furnace, any remaining incineration residues from the muffle grate and the ash grate without the use of scraping or stoking devices, in line with the progress of the incineration, by simply pivoting the surfaces.

The drawing shows an example for the realization of the invention. We designate by *m* the muffle grate pivotable around an axis *a*, by *b* the ash grate, subdivided into separate surfaces *f* which can be pivoted individually around their individual axes *e*.

The object of this invention may, in certain respects, be executed differently, as long as the essence of the invention, namely the pivotable character of the muffle grate and the ash grate, is maintained.

Patent claims:

1. Cremation furnace with pivotable grates characterized by the fact that the muffle grate which supports the coffin and the ash grate are arranged in such a way that they can be pivoted from the outside.

2. Cremation furnace according to Claim 1, characterized by the fact that the muffle grate and the ash grate are divided into several surfaces which can be pivoted individually.

Incineration furnace

Patented in the German Reich from 9 September 1933.

The object of the present innovation is a device for incineration furnaces, and it aims *i.a.* at an improvement of the combustion by a special way of feeding the combustion air.

It is known that the air feed of incineration furnaces equipped with a grate or a solid floor plate has deficiencies, and, in particular, these deficiencies are caused by the fire path in the cremation chamber, resulting from the design of the plate or the grate. Due to its massive construction, the floor plate has the advantage of storing heat. On the other hand, it has the great disadvantage that the combustion air cannot reach the central parts of the matter to be combusted, because the disintegration [of the latter] can only take place on its periphery where it is exposed to the oxygen. As the coffin with its central portions rests directly on the floor plate, combustion in that area is incomplete or retarded. This disadvantage is eliminated by the grate. It enables the air to be moved to the center of the burning coffin and thus to accelerate the incineration. In this case however, there are problems as well:

1. As the grate is open, the gas distribution of the fuel gases within the muffle can no longer be controlled.

2. During the incineration of the inner, combustion-resistant parts of the matter to be incinerated, excess air enters the furnace through the openings on the sides of the grate, cooling down the furnace.

3. The grate has a low heat-holding capacity.

Still, furnaces with solid floor plates have been built with the combustion air being blown from the side and from above by means of nozzles onto the object to be combusted.

This kind of air feed is considerably more-effective, but we still have the disadvantage that the object to be combusted is exposed initially to the combustion air only at its top and sides; air supply to the bottom part of the combustion object is, however, absent. It is at this point, though, that the air feed is highly effective, because the flames generated there will envelop the combustion object from all sides and thus enshroud it completely.

Hence, this invention plans to feed combustion air through nozzles mounted in the floor plate. For that reason, the floor plate is equipped with valley-like depressions which give it a grate-like appearance. The air nozzles are located between the grate ridges.

It is expedient to build the floor plate from individual bricks that by their shape and their arrangement confer a grate-like design to the plate. The bricks are hollow to contain the compressed-air tubes. Air feed to the nozzles is de-

signed in such a way that the nozzles can be controlled individually. For this function, the nozzles can be arranged in groups.

If arranged in accordance with this invention, the compressed air coming from the nozzles will create strong flames beneath the coffin, leading to a strong heating of the grate plate and to a good storage of the heat on account of the closed design of the floor plate. The latter effect is important because it contributes to a considerable reduction in the duration of any succeeding incinerations.

The drawing shows an example of the implementation. Fig. 1 is a vertical section of the furnace and Fig. 2 is a top view of the floor plate.

Here, we designate as *a* the bricks making up the grate plate, *b* the support of the furnace itself, *c* the muffle walls, *d*, d_1 the compressed-air tubes, *e* the corresponding conical gaskets, *f* the air channels in the bricks, *g* the air-discharge holes in the nozzles.

In Fig. 2, the bricks are numbered 1 to 20.

The shaped bricks shown in the form illustrated here have slanted roof-like surfaces on both sides which create the grate-like shape of the floor plate. The nozzles set into these bricks open up into the depressions between the individual bricks in such a way that the air jet strikes the combustion object directly. This brings about the most-effective and most-economical use of the combustion air. Moreover, the nozzles are staggered with respect to one another producing a complete and uniform air feed about the matter to be combusted.

This arrangement has the additional advantage that, on account of the nozzles being set into the slanted surfaces of the grate plate, they are protected against being accidentally covered by the combustion matter above. The nozzle orientation, moreover, makes it possible, when the ash is recovered, to blow away the fine fly ash, which is then sucked up by the draft of the chimney.

The channel-like depression *f* of the bricks (Fig. 2) can be limited to the length of one brick, such as Bricks 6 and 10, or extended over several bricks, such as Bricks 1 and 5 or Bricks 13 and 17.

In each of these cases, only one tube d_1 can serve for the adduction of compressed air, whereas each separated brick must obviously have its own connection to the air feed.

The easily manufactured bricks can be replaced conveniently in the case of any repair made necessary by heat wear or mechanical damage (emplacement of the coffin), without loosening the constitution of the grate plate.

Patent claims:

1. Incineration furnace with a floor plate closing the lower part of the incineration space and with air nozzles directed towards the incineration object, characterized by the fact the floor plate consisting of shaped bricks (*a*) presents a grate-like surface and by having nozzles (*g*) discharging into the depressions between the grate ridges.

2. Incineration furnace in accordance with Claim 1 characterized by the fact that the shaped bricks (*a*) are hollow for the insertion of the compressed-air tubes.

3. Incineration furnace in accordance with Claims 1 and 2 characterized by the fact that the air nozzles (*g*) are arranged so as to be controllable individually or in groups. [Document 153]

Description
(Attachment 2 to today's application)

Continually operating corpse-combustion furnace for large-scale operation

The collection camps in the occupied eastern territories set up on account of the war and its consequences with their inevitably high mortality do not permit the interment of the large number of deceased camp occupants. There is, on the one hand, a shortage of space and labor, and, on the other, the risk of exposing the vicinity, near or far, to the dangers presented directly or indirectly caused by any burial of the deceased, many of whom have succumbed to infectious diseases.

The need thus exists to eliminate safely, quickly, and hygienically the corpses occurring frequently in large numbers. In that case it is obvious that one cannot proceed in accordance with the legal requirements in force in the Reich territory. Hence, it is not conducive to incinerate only one corpse at a time, and such a process cannot be carried out without post-heating or additional heating. Rather, several corpses must be cremated together on a continual basis, and over the total duration of the incineration process the flames must act directly on the corpses to be cremated. A separation of the ashes of the corpses cremated concurrently cannot be undertaken; the corpse ash can only be recovered en masse. Hence, in the case of installations which serve as a means for the elimination of corpses as described above, one cannot speak of a cremation (*Einäscherung*); in fact, we are dealing with corpse combustion (*Leichenverbrennung*).

To carry out this combustion – in line with the viewpoints exposed above – in some of these camps multiple-muffle furnaces were erected which still had to be loaded and operated sequentially. For this reason, these furnaces are not en-

tirely satisfactory, as the combustion in them does not proceed quickly enough to permit the elimination of the large numbers of corpses generated continually within a short period of time.

Such an objective can only be achieved by means of furnaces which can be loaded continuously and operate in the same way. One might think for example of tunnel furnaces. In such an installation, the corpses to be burned would be loaded at the front of a long and internally heated furnace onto a moving device which moves lengthwise through the furnace, with the corpses being conveyed from a preheating zone into the combustion zone, and yielding the corpse ash at the other end of the furnace. Such a construction, however, is rendered difficult by the problem encountered on other occasions of keeping the moving metal parts – exposed to the effect of fire or flue gases – continually in motion, even if – as in the present case – these moving parts are covered to the extent possible with fireclay or other refractory substance. A further difficulty – in the case of combustion equipment operating, as in this case, with a draft, *i.e.* with different air or gas pressures in the various sections – is the task of securing the moving parts to the stationary ones to the greatest extent possible. Moreover, such units would require a permanent supply of power to actuate the moving device. Finally, the arrangement of the flue-gas ducts etc. would be complicated, which means that, for all these reasons, tunnel furnaces are not recommended for the combustion of corpses.

In an effort to avoid the disadvantages of muffle or tunnel furnaces while conserving all the advantages of continuous loading and operation even in the case of corpse-combustion furnaces, together with a most-efficient use of the required fuel, this invention proposes a furnace operating continuously in which, by avoiding structural elements which would have to move through flames, the movement of the corpses introduced at the top end of the furnace would take place automatically within the furnace. The corpses slide by gravity into the heated furnace onto chutes shaped and inclined in a suitable manner and then further down, catching fire in the process and finally burning out and turning into ash at an appropriate point within the furnace.

Fig. 1 shows the vertical section of an example of implementation.

Fig. 2 is Section A-B shown in Fig. 1.

The invention concerns, for example, a furnace with several internal chutes inclined with respect to the horizontal – the drawing shows three such possible chutes, labeled *a*, *a1*, *a2* – in a zig-zag-like arrangement. Each chute consists of several longitudinal beams *b* made of fireclay, which are supported by arched ribs *c* mounted beneath for better service life. Between the longitudinal beams *b* are located transverse bricks *d* in such a way that each chute surface is in the form of a grate. The longitudinal fireclay beams rest with their upper end in the external brickwork *e* of the furnace; the lower end is held by suitable refractory brickwork arches *f* placed transversely. The upper chutes are individually surmounted by a vault *g*, inclined from the horizontal as well, which possesses openings. The covering of the front part of the uppermost chute does not contain such openings.

At the top, where a suitable platform *h* or similar has been arranged, the uppermost chute has, at its top end, a sufficiently wide feed opening *i* which is normally closed by a self-sealing trap *k* extending into the antechamber. The corpses to be burned are loaded transversely through this trap onto the uppermost chute *a*. In order to enable such a transverse loading to be effectuated, the furnace is built to a corresponding width. The loading pace of the individual corpses to be burned in the furnace is determined by the progress of the overall combustion which is, as we have already stated, to be accelerated in the best possible way by the configuration of the furnace.

At the lower end of the first chute *a*, the reversal point, a further chute *a1* is arranged followed by the succeeding one, *a2*, and at the lower end of the last chute there is the horizontal fireclay grate *l* for the burn-out, with its ash-collection chamber below. In front of this burn-out grate there is the flame-generation section *n* which can be designed at will as a flat grate, a stepped grate, a generator, a gas or oil heater or in some other way, depending on the fuel which has to be used. The path of the flame and/or the combustion gas is arranged in such a way that, aside from the burn-out grate *l*, the grate-like chutes and all perforated vaults enable the flames and the combustion gases to move upwards. At the upper end of the furnace, opposite the loading opening *i*, we have the exit *o* of the spent gases which are to be removed and taken to chimney *p* in a suitable manner. Obviously, the flue gases can be led through an appropriate flue-gas preheater (not shown) before entering the chimney in order to make use of the heat they contain for preheating the combustion air.

On their way through the furnace, the corpses to be burned are exposed to the flames and/or combustion gases moving in the opposite direction. Multi-part fireclay slides *q*, set into the reversal points at the lower ends of the upper chutes *a*, *a1*, *a2*, and operable from the outside, allow the retardation or the interruption of the passage of the corpses through the furnace. Moreover, suitably arranged stoking openings *r* allow intervention from the outside in case of caking or adhesion of the objects to be combusted. To the greatest extent possible, ash generated inside the furnace during combustion is to fall into the ash-collection chamber through the openings in the chutes *a*, *a1*, *a2* and in the ceiling vaults. Any ash that might collect along the way on brickwork sections can be removed from the outside through suitable ash-cleaning openings *s*. The major portion of the ash will collect below burn-out grate *l* in the ash-collection chamber mentioned where its surface is permanently exposed to the heating gases in such a way that any uncombusted remains of the objects to be burned can keep on burning and burn out in this ash space. Through appropriately arranged air channels *t* opening to the inside of the furnace sufficient air supply along the whole way of the combustion objects through the furnace is assured for the promotion of the combustion process of the corpses. This air may also be preheated in a flue-gas/air preheater (not shown in the drawing). The supply of cold or preheated air may be performed under pressure in order to obtain at all times good turbulence of the flue gases.

It is also possible to equip the furnace, at the locations where stoking openings *r*, as shown in fig. 1, are provided, with additional loading openings *i* with

self-sealing traps *k*, if the furnace is to be operated at a reduced capacity from platforms located there. In that case, depending upon the desired degree of capacity reduction, one or both of the multi-part fireclay slides *q* can be closed.

Patent claims:

1.) A continually operating corpse-combustion furnace for large-scale use, characterized by the fact that within it are arranged several grate-like chutes (*a*, *a1*, *a2*), inclined longitudinally against the horizontal, following one another in a zig-zag-like manner; upon them, the corpses to be burned, fed through the upper loading gate (*i*) and entering the furnace and descending under their own weight, are ignited by the combustion gases which move in the opposite direction, [with the corpses] burning out and turning into ash upon the ash grate (*l*) placed at the lower end of the lowermost chute (*a2*).
2.) A furnace in accordance with Claim 1.) characterized by the fact that the chutes each consist of several fireclay beams (*b*) with transverse supporting bricks (*d*) between them, the beams being supported by arched ribs (*c*) located below them.
3.) A furnace in accordance with Claims 1.) and 2.) characterized by the fact that the upper chutes (*a*, *a1*) are surmounted by perforated vaults (g).
4.) A furnace in accordance with claims 1.) to 3.) characterized by the fact that ash-removal openings (*s*) are installed above each of the vaults (*g*).
5.) A furnace in accordance with Claims 1.) and 2.) characterized by the fact that at the reversal points at the lower ends of the upper chutes (*a*, *a1*) fireclay slides (*q*) moving and operated sideways have been arranged to slow down or interrupt the passage of the corpses.
6.) A furnace in accordance with Claims 1.) to 4.) characterized by the fact that, within the chutes, channels (*t*) have been arranged for additional air supply.
7.) A furnace in accordance with Claims 1.) to 6.) characterized by the fact that instead of stoking openings (*r*) introduction gates (*i*) with self-sealing dampers (*k*) have been arranged in order to be able to feed and operate the furnace at reduced rates from platforms located there. [Document 155]

Martin Klettner of Recklinghausen has been named as inventor.
J.A. Topf & Söhne, Wiesbaden.

Process and device for the combustion of corpses, carrion, or parts thereof

Patented in the territory of the Federal Republic of Germany from 24 June 1950.

Patent application published on 31 October 1950.

Patent issuance published on 13 November 1952.

The invention concerns a process for the burning of corpses, carrion, and parts thereof by combustion air heated in a recuperator as well as a device for the implementation of the process.

Nearly all incineration processes known today employ combustion air heated in a recuperator for the burning of corpses. In line with all combustion processes of heat technology, the combustion process has to be facilitated by preheating the air to very high heat levels, thus increasing the combustion temperature.

The heating value of a corpse, or its combustion value, has in the past been judged basically on the fat content of the corpse. Some of the CH (hydrocarbon) compounds (fats) exhibit very low ignition temperatures and burn at very high temperatures. As opposed to this, in the absence of pure fats, *i.e.* of pure CH compounds, it has so far been impossible to burn exothermally the CH compounds containing N (nitrogen) present in the proteins. The proteins with their rather high N content (some 25%) resist combustion most-strongly. Their ignition temperature is around 800°C.

At the air temperatures of 400 to 500°C used so far, the nitrogen component of the proteins thus could not be made to lose its resistance to combustion.

It is known that only under the influence of air at 800 to 900°C can the separation of N from the CH compounds be achieved, even though the proteins are not constituted by a chemical compound of N + CH but only by one of the loose combinations of N, in line with the way this somewhat inert gas has been known to behave. One may assume that a certain amount of heat is consumed for the removal of N. However, we will never be required to produce the large amount of heat required to remove N from a true chemical compound. Moreover, the combustion of the CH compounds contained in the proteins releases nearly the same amount of heat as would be released by the combustion of equivalent amounts of pure CH compounds.

For a human corpse of about 70 kg, containing some 12 kg of C, some 2 kg of H_2, and about 0.5 kg of P, as well as some 55.5 kg of H_2O and N, we can calculate a minimum heating value of about 160,000 caloric units [kcal], to which the fuel value of the coffin must be added.

The ultimate objective of the cremation thus had to consist in taking the required amount of combustion air to a temperature of 800 to 900°C without any

additional fuel consumption, solely by using the flue gases, in order to completely burn the considerable amounts of CH contained in the proteins yet linked to N, and so to allow the combustion of any human corpse without any additional supply of heat merely by the conversion of the amounts of energy contained therein.

This objective has been reached by means of the incineration process outlined for this invention. Not only has it been possible to generate the heat required for the evaporation and removal of the water contained in the corpse, but also the heat needed for the combustion and the incineration of the corpse itself. Even if the heat lost in the waste gases is considered, significant amounts of heat still remain available to heat the furnace and/or maintain its state.

A process as discussed earlier on and as part of the invention is implemented in such a way that the corpse with its coffin is located on a grate in the muffle and exposed to an air current heated in a recuperator by a supply of heat generated by means of fuel and/or exposed to the radiant heat of the hot muffle walls for a sufficiently long time to ignite the coffin and the corpse, made combustible by the evaporation of its water content, decomposes, with the remnants burning out exothermally on a rather-small ash grate located below under the influence of the necessary combustion air which is heated by recuperation to 800 to 900°C mainly by making use of the heat value of the corpse parts. The combustion gases thus generated flow out, downwards through the burn-out grate, and mix with hot combustion air fed below the burn-out grate in order to burn the volatile components completely. The combusted gases then move directly into a recuperator, where they transfer their heat content to the combustion air such that the combustion can be maintained without any further supply of fuel.

The illustration shows a furnace for the implementation of the process.

Muffle *A*, of a size suitable for the coffin sizes involved and built in the standard dimensions, is effective as a combustion chamber, in terms of fuel economy, only provided the muffle volume is completely filled by the combusting gases. The early phase of the combustion process, which takes place exclusively in the muffle, must be terminated as such and become a drying process when the grate, consisting of only two stones, allows the remaining body parts to drop under their own weight into the actual small combustion chamber *B* located above the pivotable grate. This [terminal] point is reached when the coffin has been consumed and the head and limbs fall off. This process in the muffle requires about 20 to 30 minutes.

In the small combustion chamber, the air heated to 800 to 900°C mixes intimately with the as-yet-uncombusted proteins, removes the N from the CH compounds, and burns the CH completely at temperatures of up to more than 1,200°C. This true combustion process takes between 10 and 15 minutes. The pivotable plate can be turned, and the remaining ash falls into the third combustion space above ash grate *C*.

The necessary combustion air is heated in an air heater *D* made of fireclay or of metal to 800 to 900°C. On start-up, a hot-air gas burner *E* generates combustion gases at 1,200 to 1,300°C to preheat the air heater. Controlled amounts of

air are fed into the muffle above the pivotable plate and below the ash grate. The hot-air gas burner, too, is supplied with combustion air at 600°C max.

As soon as the furnace has reached a steady state, the gas burner is switched off, and heating of the air heater takes place only by the waste gases which can be very hot during the actual combustion on the pivotable grate where the proteins burn actively.

The new process allows reducing the overall duration of the incineration by up to 45 minutes, with 30 minutes being often observed.

The ash quality can be called entirely combusted, free of germs; it has such a low volume that the normal urn will rarely be filled completely.

Patent claims:

1. A process for the combustion of corpses, carrion, and parts thereof by means of combustion air heated in a recuperative manner, characterized by the fact that the corpse with the coffin, in a muffle and resting on a grate of beams, is exposed to an air current heated in a recuperative way by making use of a fuel and/or exposed to the radiant heat of the hot muffle walls until the burning coffin and the corpse, made combustible by the evaporation of its water content, fall apart. The parts burn out exothermally on the small burn-out grate located below, with the necessary combustion air being heated to 800 – 900°C in a recuperative manner primarily by the combustion heat of the body parts. The combustion gases being formed flow out downwards through the burn-out grate, mixing with hot combustion air added below the burn-out grate to achieve complete burn-out of the volatile components. The spent gases are taken directly into the recuperator, giving up their sensible heat to the combustion air, thus allowing the combustion to be sustained without any further fuel supply.

2. A furnace for the combustion of corpses, carrion, and parts thereof, in a manner described in Claim 1, by means of combustion air heated in a recuperative way, and consisting of a burn-out grate which can be folded out of the way or retracted and which is located below the grate-like beams of a muffle, characterized by the fact that the grate consists of only two beams and is located above a funnel-shaped floor, the inclined walls of which serve to move the coffin and body parts onto the burn-out grate, which can be folded out of the way or retracted, [further characterized] by the presence of air outlets for the primary air feed above the burn-out grate and by the presence, in the space below the burn-out grate, of spent-air-evacuation outlets towards the recuperator, of a hot-air gas burner for temporary heating of the recuperator, and of feed outlets for secondary air. This space is also equipped with a foldable and, in view of the progression of the combustion, correspondingly smaller grate for the final burn-out.

3. A furnace in accordance with Claim 2, characterized by the fact that the combustion chamber is furnished with a relatively thin cladding of low heat capacity and is surrounded by a thick layer of insulation.

Printed matter consulted: German Patent No. 669 645.

Attached: 1 sheet of drawings. [Document 160]

4. Topf Waste Incinerators

Topf's activity in this sector of public health where combustion devices of various types were employed can be judged from a 1940 publicity brochure, of which I translate the essential part:[107]

> *"PUBLIC HEALTH AND HYGIENE constitute the starting point for the very-careful treatment of special questions which our* ***furnace-construction department*** *has been dealing with for decades. Our special furnaces hence aim for the effective fight against the spread of disease.*
>
> *Prevention is better*
>
> *Our technical and scientific knowledge together with our considerable practical experience have enabled us to accomplish a complete destruction of the germs present in hospital refuse, garbage, or similar substances, by the purifying power of flame.*
>
> *Topf furnace construction*
>
> *In this field, we have been able to profit from experience gathered over sixty years in the area of combustion technology and heat economy. The quality of our special designs shows up in an odorless and nearly smokeless combustion and in the most-efficient use of the fuel, i.e. in the flawless operation which these furnaces exhibit in terms of heat economy.*
>
> *TOPF waste incinerators – for gas, coal, oil or electrical firing – thus operate not only technically without reproach but also in the most-economical manner.*
>
> *Refuse destruction for hospitals*
>
> *Hospitals, clinics and private sanitariums increasingly tend to use* ***special furnaces for the destruction of patients' refuse****, bandage remnants, or amputated parts. (Boilers for a central heating system are not suitable for these applications.) The furnaces require only little space and low attention; hence they are suitable for smaller as well as larger establishments.*
>
> *Management of industrial refuse*
>
> *The use of special furnaces for refuse elimination in large industrial sites has been progressing actively over the last decade, in view of the fact that storage of refuse, for example, requires much space and has unhygienic consequences. Moving such substances requires much labor, time and money. Combustion of such refuse thus leads to savings and also allows the heat released to be used for the production of hot water or space heating.*
>
> *Value conservation*
>
> *The Four-Year Plan has taught us to pursue the recovery even of small amounts of valuable raw materials. Hence, we are dealing here not only with refuse destruction but also with the preservation of the materials contained, which represent valuable contributions to our economy.*
>
> *Beyond the significance of this destruction of refuse for industrial locations, it has assumed a steadily growing significance at state enterprises, utility services and municipalities. Our specialized products have evolved in line with these requirements and are being used in a great variety of applications:*
>
> *1. Furnaces for the combustion of cables*

[107] RGVA, 502-1-327, pp. 161-165; cf. Document 161.

Such a device allows the complete recovery of the valuable metals. The furnace has been conceived in such a way as to allow the concurrent separation of copper and lead.

2. Waste incinerators

These furnaces find their application in municipalities. (The ash constitutes a promising fertilizer.)

3. Wreath incinerators

These devices constitute a valuable tool for cemetery management. The great number of wreaths, accumulating every day of the year and difficult to store, can be eliminated quickly. The metal of the wires is reclaimed.

4. Mattress incinerators

Such furnaces allow an efficient and hygienic destruction as well as the recovery of the metals contained in the mattresses.

FOUR TYPES OF TOPF FURNACES

The refuse-destruction furnace AV1

(Fig. 1)[108] *is easy to install. It is therefore suitable for scientific institutions, smaller hospitals, sanitariums and birthing clinics. It destroys amputated parts, test animals and patients' refuse with extremely low generation of smoke and odor. This furnace is similar to the type for the destruction of phlegm. It is clad on the outside with wrought iron, lined with fireclay bricks, and insulated with diatomaceous earth. The loading box* A *has an insulated door opening sideways. Below this box are located the hearth* C *and the ash box* D. *The rear wall of the combustion chamber is equipped with a grate of fireclay, behind which the flue-gas channel* E *is located. Flue-gas damper* F*, placed on the outside of the furnace cladding, isolates it from the chimney and allows control of the draft.*

Refuse-destruction furnace type AV2

(Fig. 2).[109] *Ease of operation, rapid elimination of refuse with low fuel consumption and low generation of smoke and odor. Very well suited for medium-size hospitals, clinics, hotels etc. This type consists of a brick housing, which solidly protects the fireclay lining and the insulation. Loading box* A *can be mounted either on top of the furnace, or it can replace the closure* V *(type AV3). Below the combustion chamber* B *there is the refractory grate* B1 *heated by the hearth* C. *This grate will accept wet refuse and other poorly combustible materials. By means of the pivotable grate* D *any remaining ash can be transferred easily to the ash chamber* E. *The flue-gas channel* F *is placed behind a fireclay grate. Damper* H *closes this channel. Tubes for air heating or coils for warm-water production may be installed in this duct.*

The furnace for the destruction of medical waste SV

(Fig. 3) has a wrought-iron facing. This facing protects the inside of the furnace from damage. [The furnace] *contains the gas burner* A *and the loading box* B. *The fireclay plate* P *isolates the combustion chamber* C *from the post-combustion chamber* D *and the flue-gas channel* E*, which leads to the chimney. The cardboard containers of the phlegm to be destroyed are fed through the loading box onto the fireclay plate, on which they burn. The post-combustion chamber*

---

[108] Page 1 of Document 161 contains a photo of the device, p. 4 the vertical and horizontal sections.

[109] *Ibid.*, p. 4, and Document 162.

ensures a good combustion of the waste gases and thus an odorless and smokeless operation. Flue-gas channel damper F *is located outside the furnace facing and is used to regulate the draft. Between the metal facing and the fireclay brickwork there is an insulating layer of diatomaceous earth to reduce heat loss.*

The furnace for the combustion of refuse MV
(Fig. 4) destroys rapidly and safely without smoke or odor and with a minimum amount of fuel the refuse which is generated daily in such locations as warehouses, industrial establishments, hotels, market halls etc. The furnace has a brick lining with a solid wrought-iron facing. Before use, the furnace is preheated to operating temperature by means of a small auxiliary burner F. *Moist refuse is fed through door* B *onto the fireclay grate* C *and dry refuse is loaded through box* A *onto grate* D. *After combustion, the pivotable grate* E *easily allows transferring the ash to the ash box* G.
The quality and productivity of Topf furnaces have been confirmed by the following report:
'Over the past four weeks, the municipal refuse-elimination service has delivered enormous mountains of old sofas and mattresses which had to be destroyed as quickly as possible within 24 hours. On that occasion, our furnace has operated continuously, burning 120-130 mattresses in 24 hours and producing enormous quantities of wire springs.'"

5. Topf Cremation Furnaces for Concentration Camps

Towards the end of the 1930s, Topf as well as other German companies – in particular Hans Kori of Berlin (see Chapter 11) and Didier-Werke, likewise of Berlin – began to work on cremation furnaces for concentration camps using a simpler design than the one used for civilian settings.

Topf Co. designed seven furnace models for this application and erected some of them:

1. coke-fired cremation furnace with one muffle
2. oil-fired mobile cremation furnace with two muffles
3. coke- or oil-fired cremation furnace with two muffles
4. coke-fired cremation furnace with two muffles placed opposite each other
5. coke-fired cremation furnace with two muffles, Auschwitz Type
6. coke-fired cremation furnace with three muffles
7. coke-fired cremation furnace with eight muffles

In this chapter I will discuss the first four types; the Auschwitz-Birkenau Furnaces will be addressed in Chapters 6 & 7.

5.1. The Coke-Fired Cremation Furnace with One Muffle

On this type of Topf Furnace, two documents have come down to us which enable us to describe its design and operation:

1. The drawing "Incineration furnace with one muffle" produced by Topf on 8 January 1941 for the SS New Construction Office (*SS Neubauleitung*) of the

Mauthausen Concentration Camp labeled with the Number D58173 (Documents 163-163c).

2. The cost estimate for "1 coke-fired Topf incineration furnace with one incineration chamber" prepared by Topf on 6 January 1941 for the Mauthausen Camp mentioned above (Document 164). The second part of this document concerns the proposal for "a Topf cremation furnace with one cremation chamber" which I will examine in Subchapter 6.1. Here I provide the translation of the first part:[110]

"Cost estimate of 6.1.1941
Titl.
Reichsführer SS,
Main Office Budget a. Construction,
SS New Construction Office Concentration Camp
Mauthausen.

Subject: 1 coke-fired Topf incineration furnace with one incineration chamber optional:
1 Topf cremation furnace with a double cremation chamber heated by coke
1 Topf draft enhancer in suction

Qty.	*Items covered by this estimate:*	
	Supply of a coke-fired Topf incineration furnace with one incineration chamber, with blower, comprising the following jobs and supplies: *The foundations of the furnace and of the smoke conduits must be provided by the customer in accordance with our instructions, free of charges to us.* *For the outer brickwork, bricks, sand, lime and cement. The best bricks will be selected for the furnace lining.* *The necessary fireclay, in the form of normal bricks, specially shaped bricks and wedge-bricks, Monolite piling mass, as well as the necessary mortar.* *For the insulation of the furnace, the required bricks of diatomaceous earth, the rock wool and the mortar of diatomaceous earth.* *The wrought-iron anchor bars in T, U and angled shapes, drawing rods, bolts, and nuts.* *cast-iron and wrought-iron fittings, such as:*	
1	*the closure block of the muffle in wrought iron with a Monolite lining, including the required cast-iron pulley, cable, and hand-operated crank*	
6	*closure devices, cast-iron, for the air ducts*	
1	*cast-iron door for ash removal*	
1	*cast-iron closure for the gasifier feed*	
2	*wrought-iron containers for the ash*	
1	*cast-iron door for the hearth*	
1	*wrought-iron grate, horizontal, consisting of square bars*	

[110] *Kosten-Anschlag*, BAK, NS 4/Ma 54.

Qty.	*Items covered by this estimate:*	
	with supports of the grate and the required tools	
1	*blowing device consisting of a blower with a 1.5-hp three-phase motor mounted directly and the required ducting*	
1	*wrought-iron corpse-introduction device consisting of the coffin-introduction cart and the required guide rails*	
	Furnace installation	
	Presence of a specialist for the installation of the furnace, including travelling expenses, daily allowances and social-security contributions	
	Price for item 1)	*RM 5,996*
	Kennziffer weight:[111] *1,750 kg"*	

As far as I know, this furnace never moved beyond the design stage. The description which follows is based on the above two documents and on the examination of the Topf cremation furnaces with two and three muffles which still exist at Mauthausen and Buchenwald.

The furnace (Documents 163b and 163c) is enclosed in a solid frame consisting of an assembly of T-, U-shaped and angled wrought irons (*T- U- und Winkeleisen*), anchor bars (*Verankerungseisen*), drawing rods (*Anker*), bolts and nuts. The dimensions of the furnace are as follows:

Height (front side): 2,450 mm
Height (furnace body): 1,900 mm
Width (front side): 2,000 mm
Width (furnace body): 1,550 mm
Depth (w/o gasifier): 2,950 mm
Depth (with gasifier): 3,650 mm

The furnace consists of a vaulted incineration chamber (*Einäscherungskammer* or *Einäscherungsraum*), also called muffle (*Muffel*; No. 1[112]) which has the following dimensions:

Height: 700 mm
Width: 700 mm
Depth: 2,100 mm

By keeping in mind the furnaces with two or three muffles to be discussed later, and on the basis of the number of closures for the air channels (*Luftkanalverschlüsse*) – six – one may conclude that the lateral walls contained two air channels (*Luftkanäle*) running horizontally within the brickwork of the furnace, parallel to the muffle, to which they were connected by means of transverse quadrangular openings – presumably four, as in the furnaces with two or three muffles. These two channels formed right angles in front of the vertical channels of the discharge gases and opened up in the lateral walls of the furnace, forming two air-feed holes (*Lufteintritte*) closable at the front by two raisable cast-iron doors, like the two air-feeding channels of the post-combustion cham-

[111] *Kennziffergewicht*. The *Kennziffer* (identification number) concerned the allotment of metal by the *SS-Rohstoffamt* (raw materials office) at Berlin-Halensee.
[112] The subsequent numbers refer to Documents 163a through 163c.

bers (ash containers) of the Auschwitz double-muffle furnace. These channels served to bring air into the muffle for the combustion of the corpse.

At the top of the muffle vault, in line with its longitudinal axis, were located the openings (No. 2) of four conduits connected to the compressed-air conduit (*Druckluftleitung*; No. 3), which was in turn connected to the blower (*Druckluftgebläse*; No. 4) situated next to the furnace.

The muffle was closed at its front end by a closure (*Absperrschieber* or *Muffelabsperrschieber*; No. 5) sliding along a suitable and slightly inclined frame (No. 6). The upper part of the frame was housed in a brick structure (No. 7) some 600 mm thick, which rose 550 mm above the level of the top part of the furnace. Raising and lowering of the closure was accomplished by a manual crank (*Handwinde*) with its pulley (*Rolle*) and cable (*Drahtseil*). The closure was lined on the inside with refractory.

At the rear, the muffle was closed in its upper portion by refractory brickwork, its lower portion opened up to the generator neck (*Generatorhals*; No. 8).

Into the side walls of the muffle are set two rectangular openings (about 500 mm by 250 mm; No. 9) for the discharge gases leading into an equal number of vertical conduits, also having a rectangular section (No. 10), set into the furnace walls. These conduits passed vertically through the whole furnace and opened up into the horizontal smoke channel (*Rauchkanal*; No. 11) located underneath the furnace and connected to the chimney.

The smoke channel could be closed by means of a suitable closure (*Rauchkanalschieber*; No. 12) made of fireclay running vertically in a frame (*Rauchkanalschieberrahmen*; No. 12a) equipped with its pulley (*Rolle*) and a cable (*Drahtseil*; No. 12b).

The lower part of the muffle consisted of a horizontal fireclay grate (*Schamotterost*; No. 13) consisting of five transverse beams of refractory material (*Schamotteroststeine*; No. 14) on which the corpse rested.

Underneath the muffle was an inclined and funnel-shaped plane for the ash (*Aschenschräge*; No. 15) ending up in a narrower chamber – the ash chamber (*Aschenraum*) – where the post-combustion (*Nachverbrennung*) of the corpse parts having fallen through between the grate beams took place and which functioned in this sense as a post-combustion chamber for the solid residues (No. 16).

The glowing ash was removed by means of the appropriate scraper (*Kratze*) through the ash-removal opening (*Ascheentnahmetür*; No. 17) – located at the front part of the furnace, below the muffle closure – and was transferred into the ash receptacle (*Aschebehälter*) for cooling.

In the sidewalls of the ash chamber, there were two horizontal air channels which ran parallel to it over its whole length and were connected to it by means of transverse openings.

These two channels, which went through the brickwork between the ash chamber and the two vertical conduits for the exhaust gases, opened up at the front of the furnace. These openings could be closed by means of separate covers located on the two sides of the ash-removal door, as in the eight-muffle

furnace (cf. Chapter 7). They had the purpose of supplying air to the post-combustion chamber (ash chamber).

In front of the rear part of the furnace there was a maintenance access (*Schacht*; No. 18), which had a horizontal section of 1,000 mm (width) by 1,200 mm (length) and a depth of 850 mm, through which one could reach the gasifier, housed in a brick structure measuring 1,550 mm (width) by 700 mm (length) by 1,550 mm (height).

On the upper inclined surface of this brickwork (some 800 mm in length) there was the cast-iron door for the gasifier fuel (*Generatorfüllschachtverschluss*; No. 19). The feeding chute of the gasifier (*Generatorfüllschacht*; No. 20) opened up into the gasifier.

The gasifier (*Generator*; No. 21) was a pit-like chamber closed at the bottom by means of by the horizontal grate (*Planrost*; No. 22) of the hearth, which was constituted by square steel bars (*Vierkantstäbe*) and the supports of the grate (*Rost-Auflager*). The grate measured about 500 mm by 500 mm = 0.250 square meters.

The upper part of the gasifier narrowed into a neck (gasifier neck; No. 8), which opened up behind the refractory bars of the grate (No. 14) between the muffle (No. 1) and the ash chamber (No. 16.). The gasifier, up to the fire bridge in the neck (No. 23), had a volume of about 0.250 cubic meters.

In addition to the horizontal grate (No. 22), the hearth (*Feuerung*) consisted of the cast-iron furnace door (*Feuertür*; No. 24), which was used to remove the ash and to clean out the coke slag from the grate, as well as two air openings, closed by means of raisable cast-iron gates in a manner similar to the other four described earlier, and located on either side of the furnace door, as in the case of the Auschwitz double-muffle furnace, or one above the other as in the case of the mobile double-muffle furnace (cf. Subchapter 5.2.). In this case, the lower opening fed combustion air below the hearth grate; the upper one carried air into the gasifier.

The refractory brickwork of the furnace (No. 27) had a thickness of 250 mm and consisted of normal firebricks as well as of bricks having special or wedge-like shapes (*Normal-, Form- und Keilsteine*), of Monolite mass and of refractory mortar (*Schamottemörtel*).

The insulation (*Isolierung*; No. 26) of the furnace was obtained by means of bricks of diatomaceous earth (*Kieselgursteine*), slag wool (*Schlackenwolle*) and diatomaceous-earth mortar (*Kieselgurmörtel*).

The outer brickwork (*Mauerwerksmantel*; No. 25) consisted of ordinary bricks.

The blower device (*Druckluft-Anlage*) was constituted by a blower (*Druckluftgebläse*) with its 1.5-hp three-phase motor and the necessary conduits (*Rohrleitung*). The corpse was introduced into the furnace by means of a corpse-introduction device (*Leicheneinführungs-Vorrichtung*) consisting of the cart for the introduction of the coffin (*Sargeinführungswagen*) and the corresponding rails (*Laufschienen*). This device is described in detail in Chapter 7.

The system of vertical gas-discharge channels for the flue gases of this furnace corresponds to the one used by Topf for the second and third electrical fur-

naces (cf. Documents 145 and 147), but, as opposed to these models, the discharge gases did not pass through the post-combustion chamber, and there was no preheating system for the combustion air.

5.2. The Oil-Fired Mobile Cremation Furnace with Two Muffles

This type of cremation furnace was installed at the Gusen Camp (sub-camp of the Mauthausen Concentration Camp) and at Dachau Concentration Camp. It was the improved version of a *Fahrbarer Verbrennungsofen System "Topf"* (Topf Mobile Combustion Furnace) going back to the beginning of the last century. It was, however, originally conceived as a combustion furnace for animal carcasses. A Topf brochure of the time describes it in the following words (see Document 165):

> *"The furnace described below is mobile and therefore has the advantage of being able to be taken to the object of the cremation. The furnace is indispensable in particular for major land-owners with large tracts of rangeland, because it can destroy immediately any dead animals near watering places without first transporting them over a great distance. The advantages of this furnace are ease and convenience of transport, long service life and a sturdy frame. The boiler is lined with refractory, hence radiation is minimal. This furnace can also be built with oil or gas heating."*

The furnace was completely redesigned at the end of the 1930s. Topf Drawing D55719 shows a single-muffle *Fahrbarer, ölbeheizter Topf-Einäscherungsofen* (mobile oil-fired Topf incineration furnace) with the oil reservoir mounted above the furnace structure, a blower and two burners mounted laterally (cf. Document 166). There exists also a frontal photo of a furnace with two muffles clearly showing the two burners, mounted next to the ash opening below the muffle doors. The larger conduit running below the floor comes from the blower and feeds combustion air to the burners; the two smaller tubes coming down along the edges of the furnace are connected to the oil reservoir (Document 167).

This is the basic model of the cremation furnaces which were set up at Gusen and Dachau with the modifications to be explained later.

The first one was ordered from Topf by the New Construction Office of KL Mauthausen on 21 March 1940 as a mobile, oil-heated furnace (*fahrbarer Ofen mit Ölbeheizung*), but on 9 October 1940 it was decided to convert the heating system from oil to coke.[113] Topf shipped the furnace by rail on 12 December 1940, and it arrived at the site on 19 December. On the same day, the New Construction Office sent Topf a cable requesting the urgent dispatch of a technician.[114] Topf decided to send technician August Willing for 27 December.[115] Work started the same day and was finished on 22 January 1941. The two coke gasifiers were built during the erection of the furnace[116] which went into opera-

[116] Topf, "*Bescheinigung über gegen besondere Berechnung geleistete Tagelohn-Arbeiten für Firma: SS-*

tion at the end of the month.[117] The first load of coke was fed on 29 January.[118] The furnace parts are listed in the bill of lading of 12 December 1940 (Document 168). Concerning the conversion there is a Topf invoice dated 5 February 1941 (Document 169).

The furnace at KL Dachau was handed over even earlier, as we can see from a letter written by Topf to the New Construction Office at that camp, dated 25 July 1940, which states, *i.a.*:[119]

> *"We wish to mention that KL Dachau received the same furnace from us some time ago. Said camp can, however, not operate the furnace, because the necessary oil is not available. If such a furnace is urgently needed on your part, then perhaps you could take over this furnace from KL Dachau, and we would then build a stationary, coke-fired furnace for the latter camp."*

But the camp authorities at KL Dachau also decided to convert the heating section of the furnace by installing two coke gasifiers in place of the oil burners. Both furnaces, in their converted form, still exist at the sites of the former concentration camps mentioned. Initially, the conversion of the heating system of the cremation furnaces for lack of oil was decided locally, but on 17 December 1943 the head of Office CIII (*Technische Fachgebiete*; technical services) of SS Economic Administrative Main Office (*SS Wirtschafts-Verwaltungshauptamt*; *WVHA*) issued a memorandum stating:[120]

> *"In the crematoria, the consumption of liquid fuels can no longer be permitted. A conversion to solid fuel has been carried out everywhere."*

The Gusen Furnace consisted of the following parts (Document 168):[121]

Bill of lading of 12.12.1940	
	Parts of cremation furnace
1	*Mobile incineration furnace with two muffles*

[122] Topf invoice (*Rechnung*) No. D 41/107, dated 5 February 1941, for the supply of a mobile oil-fired Topf incineration furnace with two muffles, to *SS-Neubauleitung* at KL Mauthausen. BAK, NS 4/Ma 54.

29 daily allowances @ 7.--	*203.--*
Traveling costs Erfurt-Mauthausen-Dachau	*46.80*
Expenses, transport of tools etc.	*13.60*
Total RM	*10,635.40*

The description which follows refers to the furnaces of the former concentration camps at Gusen and Dachau, which had been converted to furnaces with coke-fired gasifiers. It is complemented by photos illustrating the various elements making up the furnaces, taken personally on site by the author.

The furnace consists of a basic structure taken over from the oil-fired furnace, with a facing of wrought iron – consisting, in its front part, of the block containing the muffle and ash chamber (post-combustion chamber), at the rear of the gas-discharge unit (flue-gas ducts and chimney) – and two gasifiers mounted successively next to each muffle (Photos 1-3, 32f., 35-38, 45f.). Initially, the furnace was placed on metal rollers which have survived only in the rear part of the Dachau Furnace (Photos 45f.).

The gasifiers (Photos 4, 8f., 29f., 37f.) are made of bricks and measure 1,440 mm (height) × 1,130 mm (width) × 1,640 mm (length; furnace at Dachau). The brickwork is strengthened by anchor bars. In their front parts, they each have a gasifier-loading shaft made of cast iron, standard type, (270 × 340 mm; Photos 4, 8f.). On the Gusen Furnace, at the base of each gasifier at floor level, there is an air duct for the combustion air feed to the hearth grate, closed by a cast-iron door of standard type (108 × 126 mm; Photos 4, 6-8); the Dachau Furnace has two air ducts for each gasifier, one located next to the loading door of the gasifier to feed combustion air to the gasifier, the other, right beneath it, to feed combustion air to the hearth (Photo 39). The hearths are located below floor level. Access was possible through two small service pits set into the floor at the feet of the two gasifiers (at the Dachau Furnace these shafts are now protected by grates). The hearths are closed by a door of standard type (280 × 350 mm).

The refractory structure of the gasifiers is made up of 1,000 fireclay bricks and 500 kg of refractory mortar; it has a total mass of some 4,000 kilograms.

The furnace has two vaulted muffles (Photos 1, 2, 36-38) which have the following dimensions (for the Dachau Furnace):

height: 600 mm
width: 600 mm
length: 2,000 mm

The muffles are directly linked to each other by means of three rectangular openings set into the central wall (Photos 20, 22f.), and are closed at the rear by the refractory brickwork.

The Dachau Furnace has, on its muffles' vaulted roofs, outlets arranged obliquely and connected to the blower tubing (Photos 41f.); they are located on the right side for the left-hand muffle and on the left side for the right-hand one. The internal tubes are bricked into the furnace above the center wall of the muffles. In the case of the Gusen Furnace, these outlets are placed at the apex of the muffles' vaults (Photos 19, 26) as in the Auschwitz double-muffle furnace,

where two ducts are incorporated in the brickwork (*i.e.* one in each muffle). No trace of any outer tubing remains, neither at Dachau nor at Gusen.

In their lower portions, each of the muffles is limited by a grate consisting of three transverse and one longitudinal beam of fireclay (Photo 40), set at an appreciable distance from one another (some 300 mm). Below these grates are the ash chambers having in their sidewalls the openings toward the gasifiers (Photos 16, 18, 27f.).

At the front, the muffles are closed by two cast-iron doors having on the outside a little rectangular closure of an air feed, with two round inspection holes (Photos 11, 13, 43f.), and lined with fireclay on the inside (Photos 12, 14, 43). These doors are of the same type as those on the Auschwitz double-muffle furnace (600 mm × 600 mm). Below the muffle doors there are two round metal covers, welded shut, closing the openings which, earlier, had housed the oil burners (cf. Document 167).

Because the furnace was designed originally as a mobile furnace, there is no flue-gas channel underneath the floor below the furnace, as in stationary furnaces; the exhaust gas evacuation took place instead via a rectangular opening set into the rear wall of the muffle on the right, below the level of the grate (Photo 25) from where the gases flowed into a box lined with sheets of wrought iron, located behind the furnace in line with the muffle on the right side and linked directly with the chimney (Photos 31f., 45-47), and probably containing a short flue duct through which the gases reached the chimney.

The chimney consists of a square metal duct, crowned by a truncated conical socket, onto which a cylindrical sheet-metal tube is welded (see Photos 32, 47-49). This has been preserved in case of the Dachau furnaces. At the base of the chimney there is a small hearth for preheating (pilot flame), which can be closed by a suitable door (Photos 33f., 50).

Initially, the furnace possessed three blowers, located on a cart-like support, two of which fed combustion air to the muffles and the burners, respectively, whereas the third was part of the forced-draft device. The blower for this device was located at the base of the chimney and was linked to it as shown in the figure of Document 170.[123] When the blowers were removed after the furnace activity had come to an end, the corresponding connection openings were closed by welding them shut with a metal plate (Photos 34 and 47).

As the chimney at present takes up the whole space behind the rear part of the furnace, corresponding to the muffle on the left, we may assume that it was initially in a different position, as is also suggested by Document 169, which mentions a mobile chimney (*umlegbaren Schornstein von 4 m Höhe*).

The oil tank was no doubt mounted above the furnace, as shown by Drawing D55719 and as was the case for the Buchenwald triple-muffle furnace mentioned above (Photo 201). At Dachau, this tank is presently situated in a brick

[123] As stated in an undated Topf letter to *SS-Neubauleitung* at KL Mauthausen in reply to a text dated 11 November 1940 on the subject of the Gusen Crematorium, the draft enhancer (*Zugverstärkungs-Anlage*) – consisting of a draft suction device -was necessary because of the insufficient height of the chimney (BAK, NS 4 Ma/54). This was also true for the Dachau Furnace, likewise equipped with a rather short metal chimney.

structure above the gasifier on the right where it serves no useful purpose for the furnace; we may, therefore, assume that it was placed there after the liberation of the camp by persons unfamiliar with the operation of the furnace.

5.3. The Coke- or Oil-Fired Cremation Furnace with Two Muffles

On 18 June 1938, the Construction Office of the SS administration for the camps of Buchenwald and Sachsenhausen sent a request to *Gruppenführer* Eicke, head of *Totenkopfverbände* and concentration camps, asking for authorization to build a crematorium at the Buchenwald Camp. Eicke passed it on to the Head of the SS administration in Munich with a note in which he supported the request, because the increase in the Buchenwald Camp census had led to a corresponding increase in the number of deaths among the inmates, whose corpses had to be taken to the municipal crematorium at Weimar for cremation (NO-4353). The request was accepted, and authorization was granted by *Hauptamt Haushalt und Bauten* (HBB) in early December of 1939.

For the erection of this "emergency crematorium" (*Notkrematorium*) as it was called in the German administrative documents, the Topf Co. at Erfurt was contacted, and on 21 December 1939 Topf submitted to the cognizant authorities a cost estimate for "1 Topf incineration furnace, oil- or coke-fired, with double muffle and compressed-air unit, as well as a draft-enhancing unit" ("*1 öl- oder koksbeheizter Topf-Einäscherungs-Ofen mit Doppelmuffel und Druckluft-Anlage, sowie Zugverstärkungs-Anlage*") for the price of 7,753 RM plus 1,250 RM for the draft enhancer (Document 171). Attached to this was the Drawing D56570 "double-muffle cremation furnace with oil burner" ("*Doppelmuffel-Einäscherungsofen mit Ölbrenner*") drawn on the same day (Document 172).

The "Description of the structure of the new emergency crematorium building in the camp for detainees of Buchenwald Concentration Camp," written on 10 January 1940 by the New Construction Office at Buchenwald, states in this respect (NO-4401):

> *"On account of the high mortality at the Buchenwald Concentration Camp, the need has arisen for the construction of an emergency crematorium with a furnace (double-muffle furnace) heated by oil. For this, a building* [with a floor space] *of 6 by 9 m, 4 m high, is required. The furnace will be supplied and erected by J.A. Topf & Söhne Co. of Erfurt, Dreysestraße 7-9. A description of the furnace is provided by the cost estimate of Topf & Söhne Co. dated 21.12.39, as attached. The erection is pursuant to the orders given by the head of Hauptamt Haushalt und Bauten of 9 and 11.12.39 resp., Amt II/b 265 Ri/Sa."*

The document just quoted refers to this emergency crematorium and contains a "cost estimate," a "cost summary" and finally a "weight computation" of the emergency crematorium for Buchenwald, for which a price of 14,200 RM was estimated. An undated drawing (probably of December 1939) bearing the heading "Krematorium des K.L. Bu." (crematorium of Buchenwald Camp) shows

the crematorium building measuring precisely 6 m × 9 m × 4 m (Document 173).

I have found no documents concerning the realization of this project. A later project by the "Administration – Construction Office Buchenwald-Sachsenhausen" ("*Verwaltungsamt – SS Bauleitung Buchenwald-Sachsenhausen*"), undated but probably from early 1940, shows a more elaborate crematorium labeled "K.L. Buchenwald Krematorium", with outside walls measuring 14 by 12 m, consisting of five rooms. The furnace hall, however, measuring 6.50 by 4.99 m, contains a single furnace with only one muffle (Document 174). No documents are known about the realization of this project either, and witness statements are contradictory in this respect.[124] The crematorium which was eventually built at Buchenwald had a totally different layout with a half-basement and two furnaces of three muffles each (cf. Chapter 7).

Before going into the description of the oil- or coke-fired double-muffle cremation furnace, I will present the translation of the Topf cost estimate of 21 December 1939 (Document 171; NO-4448):

	Object of cost estimate	
I.	*Oil- or coke-heated Topf incineration furnace with double-muffle and compressed air unit, as well as draft enhancer including* *The brickwork housing consisting of ordinary bricks the best of which will be selected for the outer facing of the furnace, including the necessary sand and cement-lime, the fireclay material consisting of normal, shaped, and conical bricks, Monolite packing material and fireclay mortar* *For a total weight of about 10,200 kg of fireclay material* *The wrought-iron anchoring bars consisting of T, U and angle-shaped bars, anchors, bolts and nuts* *For a total weight of about 800 kg* *The fittings made of cast and wrought iron consisting of*	
2	*Pcs. cast-iron introduction doors with their cast-iron frames, the insides of the doors will be lined with tamped Monolite mass*	
2	*Cast-iron ash-chamber doors*	
3	*Cast-iron air-channel closures*	
1	*Cast-iron flue-gas damper in its air-tight guide casing, including rollers, cable and counterweight*	
2	*Pcs. wrought-iron ash containers* *The necessary stokers*	
1	*Compressed-air unit, coupled directly to a 1.5-hp three-phase motor, and the necessary ducting*	
1	*Oil-burner unit consisting of:*	
2	*Pcs. oil burners for 6 to 25 kg/hr*	

[124] Eugen Kogon affirms that "in the winter of 1940/41 a mobile crematorium was supplied to the camp, lent from elsewhere" (Kogon 1946, p. 125). According to the Buchenwald ex-detainee Erich Haase, the first furnace (with two muffles, coke-heated) was set up in the spring of 1940 (Kommunistischen Partei…, p. 80).

2	*Pcs. cut-off valves*	
2	*Pcs. manual vane pumps*	
2	*Pcs. air-pressure meters*	
1	*Compressed-air unit with a 2 ½-hp motor, coupled directly, with the necessary tubing for oil feed and return*	
1	*Oil tank for 250 liters of oil*	
1	*Wrought-iron corpse-introduction device*	
	Total weight about 1,325 kg	
	Installation of furnace	
	Delegation of technicians (3 persons) for the erection of the furnace, including daily allowances, social security contributions and travelling expenses.	
	Delegation of one supervisory engineer for erection control and start-up of the furnace	
	Freight and carriage to Site Buchenwald	
	Price of Item I RM	*7,735.-*
II.	*One Topf draft enhancer*	
	For about 4,000 m³ of discharge gas, with 3 hp three-phase motor and starter, with suction and pressure connectors and an air flap separating suction chamber from pressure chamber	
	Total weight about 260 kg	
	Price for Item II RM	*1,250.-*
	During erection, our technicians must be provided with three helpers, at no charge to us. For the listed items made of cast or wrought iron we need an authorization code with Indicator Z which must be made known to us immediately upon placement of order.	

The description which follows refers to a coke-fired furnace. The numbers in parentheses with prefix "No." refer to Documents 172 a through c.

The furnace was held together by a solid brick structure consisting of wrought-iron anchor bars (*Verankerungseisen*) having T, U or angled sections (*T-, U- und Winkeleisen*), anchoring rods (*Anker*), bolts and nuts, for a total weight of about 800 kilograms.

The furnace dimensions are as follows:

Height: 2,100 mm
Width: 2,450 mm
Length: 2,700 mm (w/o gasifier)
3,850 mm (with gasifier)

It was equipped with two muffles (*Muffel*) having the same dimensions as those of the Auschwitz double-muffle furnace:

Height: 700 mm
Width: 700 mm
Length: 2,000 mm

On the outside halves of both muffle vaults there were the nozzles (No. 2) for the air ducts coming from the blower unit. These ducts, set diagonally, were connected to the blower ducts (*Rohrleitung*) the inner part of which (No. 4) ran horizontally in the two upper edges of the furnace.

The position of the blower (*Druckluftgebläse*) is not shown on the Topf drawing but was no doubt on the side, as in the Auschwitz double-muffle furnace and the triple-muffle furnace.

Two rectangular holes (No. 5) were set into the inside wall of the two muffles for heat exchange.

The muffles were closed in front by two cast-iron introduction doors (*Einführungstüren*; No. 6) lined with fireclay.

The lower part of the muffle was made up by a horizontal grate of fireclay (*Schamotterost*; No. 7) which was constituted by five transversal bars (No. 8) of refractory material.

Below each grate we have the funnel-shaped and inclined ash plane (*Aschenschräge*; No. 9) which ended at the post-combustion chamber (No. 10) underneath; the front part of the post-combustion chamber served as an ash container (No. 11). The embers were removed by means of suitable scrapers (*Kratzer*) through two cast-iron openings for ash removal (*Ascheentnahmetüren*; No. 12) at the front of the furnace, below the introduction door of the muffle, and was transferred to the appropriate receptacles (*Aschebehälter*) for cooling.

On the inside walls of the two post-combustion chambers were two openings (No. 13) for the discharge of the spent gases, which went to a smoke channel (*Rauchkanal*; No. 14) having a section of 300 mm by 650 mm which ran horizontally in the lower part of the furnace between the two post-combustion chambers and which could be closed by means of a hermetic cast-iron damper in the smoke conduit (*Rauchkanalschieber*; No. 15) which moved in a suitable track and could be operated by means of rollers, cable and counterweight.

The smoke conduit went into the chimney (*Schornstein*; No. 16) the inner section of which measured 500 by 500 millimeters. The furnace was equipped with a draft enhancer (*Saugzug-Anlage*) for about 4,000 m³/ h of gas driven by an electric three-phase 3-hp motor.

In the rear, the muffles were closed by refractory brickwork in which there was the opening (No. 17) for the gasifier neck (No. 18).

The drawing does not show whether the gas feed came from one or two coke gasifiers. The enormous grate of the hearth, however, suggests a single gasifier centrally located in the rear part of the furnace with its neck bifurcated to feed two muffles simultaneously.

The gasifier (No. 19), placed into a brick housing (No. 25) of 1.15 by 1.15 m, was a rather spacious pit-like chamber (0.80 by 0.80 m), bounded at its bottom by the horizontal grate of the hearth (*Planrost*; No. 20) with a usable surface of 0.80 m by 0.80 m = 0.64 m² (more than twice that of the triple-muffle furnace). The hourly load of the gasifier was thus about 75 kg of coke.

Below the grate we have the ash chamber (No. 21) closed by the hearth door (*Feuertür*; No. 22). The ash chamber was concave, as in the furnaces for civilian use, which suggests that it was laid out to contain water to cool the grate and to produce water gas at the same time.

At the top, towards the inside of the furnace, the gasifier became smaller up to the fire bridge (No. 18) in the gasifier neck (*Generatorhals*; No. 17) which led into the two muffles; on the outside, there was the gasifier-loading chute

(*Generatorfüllschacht*; No. 23) closed at the top by a lid (*Generatorfüllschacht-verschluss*; No. 24).

The oil-fired furnace, obviously, had no gasifier; in the rear portion, in line with the muffles, we have instead two burners (No. 26) fed via a suitable tube from a tank (No. 27) located above the furnace (No. 28). Combustion air was brought to the burner by a further tube, connected to a suitable blower.

The furnace was made of some 10,200 kg of refractory bricks (No. 30), covered by a thick layer of thermal insulation (No. 31) and the outer brick housing.

5.4. The Coke-Fired Cremation Furnace with Two Muffles Placed Opposite Each Other

This type of furnace appears solely on a drawing for a crematorium at the Plaszów Camp near Krakow (cf. Document 175). Whether it was ever built is unknown. The date on the drawing is illegible. The crematorium had two furnaces with two muffles each, the first furnace being set parallel to the crematorium's longest wall, the second one perpendicular to it. The design of the furnaces is the same as for the eight-muffle furnace, with two opposing muffles the doors of which were located at the two extremities of the furnace itself, whereas on the sides we have two gasifiers with their access pits.

For the first furnace, the gasifiers were placed on either side of the furnace; for the second, they were in a central position as well, but on the outside wall, because the inside wall was built against the wall of the crematorium, on the other side of which there was the chimney. Each furnace had its own chimney to which it was connected by two smoke ducts. These ducts, however, differ from the layout of the eight-muffle furnace in that they came out at the front of the muffles and not on their sides which means that the discharge of the gases was located at the front part of the device, as in the single-muffle furnace.

6. The Topf Co. and the Construction of the Cremation Furnaces at Auschwitz-Birkenau

6.1. The Furnaces of Crematorium I at Auschwitz

The budget for the Auschwitz Camp, drawn up by *SS Obersturmführer* Fritz August Seidler on 30 April 1940, included an item for the construction of a new crematorium (*Neubau Krematorium*) at a cost of 15,000 Reichsmarks (RM).[125] Instead of erecting a new building, however, the equipment was eventually installed in a bunker of the former Polish artillery barracks which constituted the nucleus of the new concentration camp. The plans for the crematorium were drawn up in the week of 14 to 20 June.[126] The firm J.A. Topf & Söhne of Erfurt which the Main Office Budget and Construction (*Hauptamt Haushalt und Baut-*

[125] Kostenaufstellung für das Lager Auschwitz bei Kattowitz. RGVA, 502-1-176, p. 37.
[126] *Tätigkeitsbericht* dated 20 June 1940, for the period of 14-20 June. RGVA, 502-1-214, p. 102.

en, *HHB*) had contacted for the supply of the equipment, had already informed the New Construction Office at Auschwitz on 25 May that the drawings of the foundations of the cremation furnace would be sent within a few days, and that their erection supervisors would arrive at the camp within two weeks for the installation.[127] The furnace ordered by *HHB* was an oil-fired double-muffle furnace (*ölbeheizter Doppelmuffel-Ofen*).[127] On 10 June 1940 Topf sent to the New Construction Office Drawing D57253, executed the previous day, concerning a "Cremation furnace heated by coke and plan of the foundations" (cf. Document 202). Topf advised, moreover, that "instead of the oil firing originally planned, 2 coke generators will be mounted in accordance with the advice from your superior authority."

Topf added that this would result in a delay of the shipment and announced that the materials for the furnace would probably be shipped on 15 July.[128] Actually, Topf did not modify anything, because *HHB* decided to install at Auschwitz a furnace of a different type, patented on 6 December 1939 as an "*Einäscherungs-Ofen mit Doppelmuffel*" (cremation furnace with double muffle)[129] which had already been proposed to the New Construction Office at Auschwitz in April. The pertinent cost estimate (*Kostenanschlag*) of 17 April 1940 in fact referred to the "supply of a coke-fired Topf cremation furnace with two muffles and compressed-air unit, plus 1 Topf draft-enhancing unit."[130]

The New Construction Office replied on 15 June by cable, stating that supply was "extremely urgent" (*äußerst dringend*).[131] On 20 June, Topf confirmed receipt of the cable and stated that the firm had shipped the furnace materials in the fastest way available and that the technicians would arrive at Auschwitz towards the middle of the following week. Erection time of the furnace was 16 days.[132] The refractory materials were shipped on 22 June by the firm Collmener Schamottewerke G.m.b.H. of Colditz on Topf's account.[133]

In the week of 21 to 27 June, the New Construction Office continued work on the design of the crematorium (*Bauabschnitt IV*) which constituted the last of the four construction sectors under the responsibility of this office.[134] Revamping of the former bunker began the following week (opening of windows, erection of partitions) and the materials[135] shipped by Topf on 1 July arrived as well.[136] Between 5 and 11 July, brick-laying and concrete work continued, and the furnace foundations were poured. The Topf technicians arrived at Auschwitz and began work immediately.[137]

[137] *Tätigkeitsbericht* dated 12 July 1940, for the period of 5-11 July. RGVA, 502-1-214, p. 97.

Work on the rebuilding of the crematorium and on the brickwork of the furnace ended in the week of 19 to 25 July;[138] a few days later, the *Bauleiter*, SS *Untersturmführer* August Schlachter sent Topf a cable requesting the shipment of the items still missing: blower, draft enhancer, gasifier doors, corpse-introduction cart, rails and pulleys for the closure of the smoke conduit.[139] On 29 July, Topf confirmed receipt of the telegram and informed the New Construction Office of the imminent arrival of the requested parts.[140]

In all probability, drying-in of the furnace began as soon as the brickwork was in place. The test cremation was, in fact, carried out on 15 August. The activity report (*Tätigkeitsbericht*) for the period of 9-15 August states:[141]

> *"The entire erection of the crematorium, including the cremation unit as such, was completed so that at the end of the week of this report the first cremation could be realized."*

A further, undated, document mentions the exact date of 15 August:[142]

> *"This construction office certifies that the erection work for the cremation furnace was completed on 15 August 1940. The test cremation of the first corpse took place the same day."*

On 27 August, Topf asked the New Construction Office for payment of the invoice covering the cremation furnace, in an amount of 10,679 RM, or at least a down payment of 9,000 Reichsmarks.[143]

On 16 September, the New Construction Office forwarded to Office II of *HHB* Topf's invoice with the following comment:[144]

> *"The cremation installation is completely finished and has been in operation for weeks. As no malfunction at all has been noted, complete payment for the unit should not encounter any problems."*

Two days later, Topf sent out a demand for the payment of the total amount or of the down payment,[143] followed by another, merely for the down payment[145] on 23 September and a further demand on 30 September.[146] On 2 October, *Bauleiter* Schacht informed Topf that he had forwarded to *HHB* Topf's request for the down payment of 9,000 RM, asking the Erfurt company to get in touch with that office directly.[147] When Topf followed the advice and contacted *HHB*, there was an unpleasant surprise: The invoice of 27 August 1940, in an amount of 10,283 RM[148] had not reached this office yet.[149]

At the end of September, the crematorium still did not possess a room for autopsies. On 28 September, the *SS Standortarzt* (camp physician) sent camp

[146] *Ibid.*, p. 212.
[147] *Ibid.*, p. 211.
[148] It is not known why an amount of 10,283 RM is mentioned here instead of 10,679 RM.
[149] Letter from *HHB* to *SS-Neubauleitung* dated 4 November 1940. RGVA, 502-1-327, p. 207.

command a detailed request for the installation of such a facility, explaining that "in the case of deaths the causes of which are not clear, autopsies are to be carried out, in particular for executions by shooting or in the case of fatalities caused by external force."[150]

The camp command turned to the New Construction Office, which replied directly to the *SS Standortarzt*, explaining that an autopsy facility could not be installed immediately because certain essential pieces of equipment – such as the dissecting table – were not yet available.[151] On 7 November 1940, Schlachter informed Topf as follows:

> *"The present level of usage of the combustion unit installed here by your company has shown that the unit is in fact too small."*

The New Construction Office intended to double the cremation facility and asked Topf to send a representative to Auschwitz to discuss the matter on site.[152] On 13 November, Topf replied that engineer Prüfer would be at Auschwitz on the 16th with a cost estimate and the drawings of the second furnace. On the same day, Topf drew up two quotations concerning the second furnace (cf. Document 193), which was proposed for a price of 7,753 Reichsmarks. In the letter of transmittal, likewise dated 13 November, Topf – assuming that the second furnace would be connected to the same chimney – judged another draft enhancer (*Zugverstärkungs-Anlage*) to be superfluous because the existing one was sufficient for an alternating operation of both furnaces, which could, however, be in operation at the same time as well.[153] On 22 November, the New Construction Office sent a request to Office II C2 of *HHB* asking for the authorization to install the second furnace, giving the following justification:[154]

> *"The operation of the crematorium in the past has shown that, even in the relatively favorable season, the furnace with its 2* [cremation] *chambers is too small. The camp command and Political Department have therefore approached the New Construction Office with the urgent request to enlarge the unit by 2 chambers."*

The request was granted, and Topf went to work: on 30 November, Drawing D57999 showing the positioning of the second furnace in the crematorium was prepared (cf. Document 204). On 5 December, this drawing was sent to the New Construction Office, and Topf informed them that the refractory and insulating materials for the second furnace had already been shipped;[155] some of these materials, however, were shipped later: 2 refractory plates left on 20 December[156] and 50 bags of mortar mix the following day.[157]

In early January of 1941, the situation in the crematorium became critical. On 8 January, Schlachter sent Topf an alarming letter in which he declared:[158]

> *"New Construction Office has already informed you by telegram that the first furnace unit shows damage due to intensive usage and hence can no longer be operated to capacity. The enlargement of the unit is therefore imperative. You are requested to inform us by telegram as to when you will begin to take the preliminary steps for an enlargement."*

The installation of the new cremation furnace, constituting as it did an enlargement of the crematorium, was therefore rightly designated by the New Construction Office as *Erweiterung des Krematoriums* or *Krematoriumserweiterung*.

On 10 January 1941, Topf confirmed receipt of Schlachter's cable concerning the damages to the first furnace and the urgency of the installation of a second one and reported that all the necessary materials for the construction of the furnace had already been shipped, whereas shipment of the metal parts could take place only after the end of the goods embargo (*Gütersperre*). On the subject of the furnace damage, Topf stood ready to dispatch its technician Wilhelm Koch for repair work.[159]

In the meantime, the situation worsened. On 13 January, Schlachter informed Topf that the Monolite grates (*Monolitroste*) of the muffle and the internal walls (*Innenwände*) of the gasifiers had burned through (*durchgebrannt*) and demanded the immediate dispatch of a technician.[160] In line with bureaucratic practice, Topf replied two days later by sending a cost estimate (*Kostenanschlag*) for providing a technician (*Monteurgestellung*).[161] On 21 January, Schlachter informed Topf that the order for the repair work (*Reparaturarbeiten*) would be issued by the camp administration (*Verwaltung*) within the next few days and added the following order:[162]

> *"Furthermore, 2 generator closures must be supplied a.s.a.p. for the repair work, as the old ones are completely burned through."*

The camp administration returned the Topf cost estimate of 15 January to the New Construction Office, explaining that the transfer certificate (*Übergabe-Verhandlung*) for the crematorium was still missing, without which it was impossible, for reasons of authorization, to pay for the repair work.[163] On 29 January, Topf confirmed receipt of the order from the New Construction Office for "2 two cast-iron closure doors for the generators" for the price of 180 RM and stated that shipment would take place eight weeks later.[164] Repair work was carried out much sooner, though, while the second furnace was being erected. In his report of 1st March, Schlachter, in fact, wrote that everything had been repaired.[165]

[164] RGVA, 502-1-327, pp. 183f.
[165] *Tätigkeitsbericht* dated 1st March 1941, for the period of 23 February -1st March. RGVA, 502-1-214, p. 67.

The parts for the second furnace were shipped by Topf on 17 January 1941; the total weight came to 3,193 kilograms (cf. Document 197), and two days later the two cement counter-weights (*Zement-Gegengewichte*) for the two flue-gas dampers[166] followed. The weekly activity reports (*Tätigkeitsberichte*) for this period allow us to follow in detail the work involved in the installation of the new unit:

– Week of 26 January – 1st February: "In the crematorium, the foundations of the new furnace were poured and the partition[167] was erected using insulating bricks. Installation of the new combustion furnace was begun."[168]
– 2-8 February: "In the crematorium, work continued on the completion of the new combustion unit."[169]
– 9-15 February: "In the crematorium, the new combustion unit has been completed, except for a few minor details."[170]
– 16-22 February: "The new combustion unit in the crematorium has been completed."[171]

The next report stated again that "in the crematorium, work on the new combustion unit was completed,"[172] which probably means that the furnace was finally able to function; it is likely that the drying-in process extended over several weeks.

The new furnace had not been in operation for more than two weeks when the first technical problems arose. On 2 April, the New Construction Office sent Topf a telegram stating: "Second furnace has no draft, send technician here immediately."[173] In a letter to Topf of the same day, Schlachter explained that "the second furnace unit does not have sufficient draft which means that the combustion cannot be carried out completely."[174]

Topf replied that no technicians were available, but that the problems could be solved by the crematorium attendants: The two units were connected to the same suction device (*Saugzug-Anlage*) and that, when both were in operation simultaneously, the second one, being farther away from this unit, would have a lower draft. It was necessary, first of all, to close the two flue dampers of the first furnace and to set those of the second one, then to open those of the first one again and to balance the two.[173]

In early June, the second furnace was in operation "nearly every day" (*fast täglich*);[175] this probably led to a deterioration of the chimney, which was re-

paired, in the week of 23-28 June, by strengthening it with angle irons (*Winkeleisen*) and tension bolts (*Spannschrauben*).[176] It appears that over the following months, the two furnaces were not able to cope with the number of deaths among the detainees in the camp, even though the Auschwitz Camp was still rather small.[177] Towards the end of September, Topf received a verbal order for "a double-muffle Topf cremation furnace with blower, introduction cart and rotatable platform."[178]

The Topf cost estimate, dated 25 September, showed a price of 7,332 RM, solely for the furnace with the blower.[179] The previous day, Topf had sent the New Construction Office three copies of the operating instructions (*Betriebsvorschrift*) of the double-muffle furnace[180] and of the draft-enhancement device.[181] The two documents reached Auschwitz on 26 September as shown by the registration stamp of the New Construction Office. In keeping with bureaucratic regulations, the New Construction Office then confirmed the order by registered mail,[182] and Topf in turn confirmed this confirmation.[183] The furnace parts, having a total weight of 3,548.5 kg, were shipped by Topf on 21 October.[184]

During the month of October, mortality among the detainees rose to 85 deaths per day, and would hit 169[185] the following month. The situation was disastrous. On 11 November, *SS Hauptsturmführer* Karl Bischoff, who had taken over Schlachter's place as head of the Construction Office[186] on 1st October, sent Topf a telegram in which he informed the company that setting up the third furnace was "extremely urgent" (*äußerst dringend*), and asked when it would be installed.[187] Two days later, Topf confirmed receipt of the cable and announced the arrival of their technician for the 19th.[188] On 17 November, Topf cabled Auschwitz about the date of arrival of the technician Albert Mehr,[189] who, however, did not reach Auschwitz until 29 November because a number of difficulties had been encountered: Topf's supplier, the firm Collmener Schamottewerke, had not been able to ship the refractory for the new furnace on account of

an embargo of freight cars (*Waggonsperre*).[190] Bischoff sent this company a copy of the permit issued by *Transportkommandantur Oppeln* for the shipment of the refractory materials,[191] but the company still was not allotted a freight car.[192] Technician Mehr stayed at Auschwitz from 27 November through 4 December, for a total of 56 working hours and 14 hours of overtime.[193] As we know from a Topf letter dated 9 December, he "had finished the foundations of the new cremation furnace, as well as repair work on the two coke-fired double-muffle cremation furnaces."

In this letter, Topf confirmed the order for "providing a technician" it had received from *Bauleiter* Schlachter, announced that the Plützsch Company of Fichtenhainiken/Rositz had loaded a freight car of refractory, and stated:[194]

> *"These materials were ordered by your local KL administration as spares for repair work. We can, however, temporarily make use of these materials – which suffice for the construction of a furnace – for the new furnace and kindly ask you to inform us in time to allow us to dispatch a technician to the site for the erection of the furnace."*

The freight car with the refractories of the Plützsch Company left on 12 December,[195] but arrived at Auschwitz only on 2 January 1942.[196] Topf declared themselves to be ready to dispatch technician Koch to Auschwitz on 5 January 1942.[195] The Central Construction Office changed the date to 5 February, but on 1st February Koch's departure was postponed to a date yet to be determined.[197] On the other hand, a Topf technician charged the Central Construction Office for 86 hours of work done at the crematorium between 18 and 26 December 1941, including travel and 12 hours of overtime: Who was this technician and what kind of work did he do?

The existing documents, being incomplete, do not allow us to answer that question with certainty. Probably, Topf, pursuant to the Central Construction Office request for "providing a technician" mentioned in the letter of 9 December 1941, had once again sent their technician Mehr to Auschwitz for more repair work on the two furnaces of the crematorium, possibly making use of part of the two tons of insulating material which had arrived at Auschwitz on 15 December 1941 on Topf's account.[198] It is also certain that a Topf technician worked in the crematorium in the latter half of January 1942, which makes an understanding of the events during that period even more difficult.

[198] RGVA, 502-1-175, p. 339.

On 9 January 1942, the head of the camp administration, ordered to do so by the camp commandant, requested the following jobs for the crematorium to be carried out by the detainee workshop of the Central Construction Office:[199]

"Make 2 flat bars 700 × 80 × 8 mm
Repair 3 furnace doors
Repair 2 grates 700 × 30 × 30"

The flat bars (*Flacheisen*) were part of the anchoring system of the third furnace, which was under construction at that time. The *Ofentüren* to be repaired could have been either the doors of the muffles through which the corpses were introduced (*Einführungstüren*) or the hearth gates (*Feuerungstüren*); the latter are more probable because two hearth grates also needed to be fixed. The work was done during the week of 14 through 21 January.[200] On 16 January the detainee workshop received the order to "cut threads on the furnace anchoring bolts" (*für die Ofenverankerung*)" and to "make a frame 50 by 50 according to instructions by technician (*n. Angabe des Monteurs*)." The job was executed between 22 and 24 January.[201] On 31 January, Maximilian Grabner, head of the Political Section, sent to the camp command the following request:[202]

"As an engineer of Topf and Sons is presently on the site for the construction of a furnace in this camp, it is requested to repair, on this occasion, Furnace No. 2 of the crematorium, which is in need of repair work."

The Topf engineer in question was undoubtedly the technician mentioned in the 16 January order to the detainee workshop, and his presence may have rendered the arrival of Technician Koch superfluous.

The repair work on the second furnace, requested by Grabner, was carried out on 4 February, as we can see from a handwritten note on his above-mentioned letter.[202] On 10 February, the detainee workshop did further repair work on two hearth gates ("*2 Türen für die Feuerung gangbar machen*"), and fabricated 4 angle irons (*Winkeleisen*)[203] which were part of the anchoring system of the third furnace. On 20 February, another freight car with refractory bricks and mortar shipped by Plützsch Co. on Topf's account arrived at Auschwitz,[204] which means that the shipment from that company which had arrived on 3 January was probably used for the repair work it was intended for.

Construction work on the third furnace ended in late March. The work-in-progress report (*Baufristenplan*) for the month of February indicates the degree of completion for the enlargement (*Erweiterung*) of the crematorium to be 90%[205] and the March report states that work had been completed 100% by 31 March.[206] This date is confirmed as well by the report on construction of buildings dated 1st April 1942:[207]

Installed in existing bunker: Cost of construction according to cost estimate I of 31 October 1941: RM 52,000, cost estimate II of 31 October 1941: RM 30,000, so far approved by decree of 25 May 1940: RM 52,000. Ref.: II/E-901/Schr.Sa. Expenses up to 28 February 1942: RM 44,210.18."*

Finally, the third furnace appears in the "Inventory plan of Building No. 47a, *BW* 11. Crematorium" drawn on 10 April 1942 by Detainee No. 20033,[208] the Polish engineer Stefan Swiszczowski who worked as a draftsman at the Central Construction Office.[209]

Topf's partial invoice (*Teil-Rechnung*) for the third furnace, made out on 16 December and stamped by Bischoff on 22 December, amounted to 7,518.10 Reichsmarks.[210] On the basis of this invoice, the Central Construction Office, on 7 January 1942 issued a payment voucher for a progress payment of 3,650 RM, which was paid out on 27 January.[211] Topf sent out a second partial invoice, likewise back-dated to 16 December 1941, which reached Auschwitz only on 22 May 1942,[212] however, showing a balance of 3,868.10 RM, the result of subtracting from the original cost estimate the 3,650 RM already paid as a progress payment by the SS administration. The final invoice (*Schlussrechnung*), again back-dated to 16 December 1941, which reached Auschwitz on 10 July 1942, shows a balance of 3,768.10 RM including a deduction of 82 RM concerning a rotatable platform (*Drehscheibe*) which had not been supplied.[213] The payment voucher for the final payment (*Schlussabrechnung*), in this amount, was issued by the Central Construction Office on 17 July 1942 and payment was effected on 29 July.[214]

During the latter half of May, work on the exterior was carried out: the yard in front of the crematorium was fenced in and provided with two wooden gates, the old pavement was replaced.[215]

After the installation of the third furnace, even-more-serious problems than before arose in the crematorium. On 13 May, the head of the camp administration requested the Central Construction Office to "repair the chimney and the

motor shed (*Motorenhaus*)[216] of the crematorium."[217] The work was carried out on 14 and 15 May; the first item did not concern the chimney as such but the "*Kaminunterkanal*" *i.e.* the flue-gas channel which linked the three furnaces to the chimney: 50 refractory bricks were replaced, using 50 kg of refractory mortar.[218] But this was only a skirmish. On 30 May, *SS Oberscharführer* Josef Pollok, acting as the local building inspector, addressed to Bischoff the following report:[219]

> *"On the chimney of the crematorium at KL Auschwitz, the chimney bracing*[220] *has loosened. This was caused by improper execution, as well as, partly, an overheating of the chimney. The braces have not been made as a framework in accordance with their purpose and are therefore useless. As the chimney already shows wide cracks which, though refilled on the outside, also extend into the brickwork in my opinion, there is the danger that the chimney may collapse under a strong wind. To avoid unforeseeable consequences, I ask the head of Central Construction Office to take immediate measures to eliminate this defect. For this purpose, it would be necessary to make sure that all braces are removed and replaced by an appropriate framework in line with good trade practice."*

On 1st June, Bischoff, in a letter to the camp command, endorsed Pollok's report and, as head of the Central Construction Office and in his capacity as local representative of the building inspectorate (*Baupolizei*), prohibited the use of the chimney on the basis of Article 365 of the civil code, as long as repair work was not carried out completely. Bischoff also asked to forward a request for repair of the chimney to the *WVHA*.[221] Sending a copy of his letter to the *WVHA*, Bischoff added:[222]

> *"The chimney has suffered from overheating on account of its continuous use (operation day and night)."*

The camp command no doubt informed the *WVHA* by cable, because on the following day, SS *Brigadeführer* Hans Kammler, head of Office Group C at *WVHA* gave the order for the reconstruction of the crematorium chimney.[223] On 4 June, Kammler confirmed the order for the immediate reconstruction of the chimney, and asked why he had not been informed in time.[224] Bischoff replied that he had already sent the respective information to the *WVHA* and that he had

started to undertake the rebuilding of the chimney as soon as he had received Kammler's radio message.[225]

In fact, the very next day, the Central Construction Office got in touch with the firm Robert Koehler at Myslowitz for the reconstruction of the chimney. Koehler explained that the new chimney should measure 25 to 30 m in height, for an internal diameter of 65 to 70 cm, but that a precise design required technical details from Topf. The Political Section, however, wished that the new chimney not be higher than 8 to 10 m and that it should be placed on the same spot as the existing one.[226]

The following day, Bischoff informed Topf that the chimney had to be rebuilt at a distance of 7 m from the old one and asked Topf to indicate height and cross-section.[227] On 6 June, Topf replied by telegram, indicating the dimensions in question – a height of 15 m and a cross-section of 0.8 to 1.0 m² – and announced the mailing of a drawing.[228] This drawing – No. D59463 – was delivered at Auschwitz on 12 June. Meanwhile, the Central Construction Office had decided to move the new chimney by 10 m and asked Topf for the dimensions of the corresponding flue-gas channel (*Rauchkanal*).[229] A list dated 13 June shows that the materials required for the rebuilding of the chimney and the flue-gas channel came to 27 tons of refractory bricks of normal size and a Seger-cone index of 26 to 28, for temperatures up to 1,200 to 1,300°C, as well as 2.7 tons of refractory mortar, 25 tons of facing bricks and 100 bags of cement.[230]

On 16 June, the Koehler Company presented their proposal to the Central Construction Office: for the construction of a chimney measuring 15 by 0.8 by 1.0 m they demanded 3,650 RM, for the installation of the 12 m flue-gas duct, 1,050 RM, and for the demolition of the old chimney and removal of the rubble 860 Reichsmarks. The work required 24,210 bricks, 6 m³ of slaked lime, 4,400 kg of cement, 20 m³ of sand, 16 m³ of gravel, 27 tons of normal refractory bricks 25 by 12 by 6.5 cm with a Seger-cone index of 28 to 29, 2,700 kg of refractory mortar, 70 iron steps, 6 hand rails, one lightning rod, one access door for cleaning.[231] On 20 June, Robert Koehler elaborated the structural design of the chimney[232] and the corresponding drawing.[233]

Two days later, the Central Construction Office gave Robert Koehler the official order (*Auftragserteilung*) for the rebuilding of the chimney on the basis of his offer of 16 June for a total amount of 5,560 RM,[234] but Koehler confirmed receipt only on 14 July.[235] The contract, dated 7 July (Bischoff signed it the fol-

[235] Letter from the Robert Koehler Company to *Zentralbauleitung* dated 14 July. RGVA, 502-2-23, p.

lowing day), was divided into four sections: the contract as such which mentioned the total cost of 5,560 RM, the "Special contractual conditions" which specified the immediate start of the work and its completion within four weeks, as well as a two-year warranty, the "Supplementary contractual obligations" drawn up by the Central Construction Office on 22 June and signed by Koehler on 14 July, and finally the "Assurances by the contractor concerning special obligations" signed by Koehler on 14 July.[236]

The budget for the new chimney established by the Central Construction Office on 3 July specified a cost item of 11,500 RM including the materials and work not furnished by Koehler.[237]

Various documents mention the work being carried out during the month of June. The *Baufristenplan* for this month states that the work on the chimney began on 12 June on the basis of the order placed on 4 June, degree of progress was 10% with completion scheduled for 10 August.[238] The *Baubericht* informs us that the foundations of the new chimney had been cast and brickwork had started.[239] The *Tätigkeitsbericht der Fahrbereitschaft* (motor-pool log) shows 17 trips to the crematorium by truck for the transportation of the building material and wood.[240]

On 1st July, the Central Construction Office asked the detainee workshop to fabricate 37 step irons (*Steigeisen*) measuring 25 by 25 cm – to be set into the wall of the chimney to allow access to the top – as well as 6 guard rails and a double door for the soot pit.[241] The work-sheet was passed on to the detainee workshop the following day, and the job was carried out between 2 and 6 July.[242] On 3 July, the Polish engineer Stefan Swiszczowski, Detainee No. D20033, made a new drawing of the crematorium – on the basis of his Drawing No. 1241 of 4 April – showing the positioning of the new chimney and the corresponding flue duct (Pressac 1993, Document 8 (outside of text); cf. my Document 207).

This job was realized only in part, because the flue-gas duct, having a length of 12.20 m, shown on this drawing, was connected only to Furnaces 1 and 2, whereas for Furnace 3, a further, transverse, flue-gas duct was built, 7.375 m long, bringing the total length of the ducts to 19.575 m as shown on the Koehler Drawing of 11 August 1942.[243] On the same day, the Central Construction Office prepared an explanatory report (*Erläuterungsbericht*) for the construction of the chimney, in which we can read:

243 Robert Koehler, *Rauchkanal für die Zentral-Bauleitung der Waffen-SS und Polizei Auschwitz O.S.* dated 11 August 1942. RGVA, 502-2-23, p. 18. Cf. Document 179.

> *"On account of continual and excessive operation of the crematorium and the ensuing overheating of the chimney, the latter shows major cracks presenting the danger that the chimney might collapse. Repairing the old chimney is not possible. Therefore, by telex dated 2 June 1942, head of Office Group C, SS Brigadeführer and Major-General of Waffen-SS Dr.-Ing. Kammler gave the order for the replacement of the chimney."*

The report goes on to explain that the new chimney had a square cross-section of 90 by 90 cm, and a flue-gas duct 12 m in length with a square cross-section of 70 by 70 cm and a refractory lining of 12 cm in thickness.[244] A list of materials compiled by the Central Construction Office on 4 July shows the same items as those mentioned by the Koehler Company in their letter of 16 June.[245]

In the meantime, the old chimney had not only not been dismantled but was being used intensively. In this matter, *SS Oberscharführer* Pollok sent Bischoff another report on 6 July:[246]

> *"During the building safety inspection of the work on the crematorium it was found that the old chimney has developed more cracks, both horizontal and vertical, which must result in a collapse of the chimney. This is due to the fact that the chimney has continued to be used to excess, although Central Construction Office der Waffen-SS und Polizei had prohibited its use by letter of 4 June, Bftgb. 8195/42/Po/Qu., addressed to the camp command.*
> *I ask the Head of Central Construction Office to prohibit once again continued use of the chimney and to ensure that it is demolished immediately, because otherwise the consequences would be incalculable."*

This time, Bischoff's order was obeyed: during the course of the month, the old chimney was demolished. The *Baubericht* for that month states:[247]

> *"BW 11 crematorium. Completion of the new chimney and dismantling of the damaged one including removal of the rubble. At present, laying of the new connecting channel."*

The activity report of *SS Unterscharführer* Heinz Lubitz for July 1942 confirms that the brickwork of the chimney had been completed (*Schornsteinmauern fertiggestellt*) and that the flue-gas channel had been dug and built (*Kanal ausgeschachtet und gemauert*).[248]

For the very reason that the flue channel was still being worked on, the *Baufristenplan* for that month shows a work progress of 80%.[249] During July, the trucks of the Central Construction Office made 15 trips to the crematorium for the transportation of building materials.[250]

On 24 July, the Koehler Company advised the Central Construction Office that there had been an error in their cost estimate for the demolition of the old

chimney: construction of the new chimney would cost 2,790 rather than 3,650 Reichsmarks.[251] The new and corrected offer was sent by Koehler to the Central Construction Office on 14 August.[252] Work ended in the first ten days of August, and over the whole month there were only five trips to the crematorium by the trucks of the Central Construction Office.[253] The *Tätigkeitsbericht* for the month of August states:[254]

> *"New smoke channels linked to the 3 pcs. double-muffle furnaces, covered by slab of reinforced concrete, lightning rod connected and handed over to political administration for operation. Work terminated except for finishing touches."*

The *Baufristenplan* speaks of a degree of completion of 100% as of 10 August,[255] but a memo of 7 December gives 8 August as the date of completion: between 12 June and 8 August, 688 detainees had worked on the new chimney – for a total of 7,568 working hours – plus 123 civilian workers – for a total of 1,353 working hours (both groups worked 11 hours per day). The materials used had exceeded the estimates by very little: 25,000 bricks, 6 m³ of white lime, 200 bags of cement, 31 tons of refractory bricks, 3.7 tons of refractory mortar, 66 iron steps, six hand rails, plus three liters of oil, ten liters of gasoline, 17 rolls of roofing felt and 50 liters of inert oil.[256]

Four days after the work had come to an end, the new chimney was already damaged, because the three furnaces had been operated at full load without waiting for the brickwork to dry out. On 13 August, Bischoff, referring to his telephone conversation with *SS Hauptsturmführer* Robert Mulka the day before, sent the following message to the camp command:[257]

> *"On the basis of the telephone conversation mentioned above, camp command was informed that due to a too-rapid heating of the new chimney installation of the crematorium (all 3 furnaces are in operation) damage to the brickwork has already been observed.*
> *As the start-up of the 3 combustion furnaces took place at full load before the mortar of the chimney brickwork had dried out completely, any further responsibility* [of this office] *for the building must be rejected."*

After all the exertion, the same situation as in June had come about. On 14 August, after a telephone conversation of *SS Unterscharführer* Kirschnek and Robert Koehler, the latter was called to Auschwitz by Bischoff.[258] On 19 August, Kirschnek and Koehler inspected the damage to the new chimney.[259] Three days later, Koehler, having been asked to do so (*wunschgemäss*), sent to

[259] *Aktenvermerk* dated 21 August 1942. RGVA, 502-1-313, pp. 159f., and APMO, BW 30/27, pp. 13f.

the Central Construction Office a new offer for the erection of another chimney, 15 m high, amounting to 3,100 RM, with an increase of 2,690 RM in case of employment of detainees at company expense; the building materials were offered at 4,195 Reichsmarks. The offer also mentioned the erection of another cremation furnace, as per Drawing 914 of the Central Construction Office, for the price of 12,690 Reichsmarks. But a handwritten note on this letter, dated 26 August and referring to the furnace, states: "*Kommt nicht zur Ausführung*," *i.e.* "will not be realized."[260]

The camp administration had submitted to *WVHA* the construction request for the chimney as early as 18 August, but the head of Office C VI of that office, *SS Standartenführer* Franz Eirenschmalz, made a mistake when he approved the amount of 11,500 RM, thinking that the approval referred to the chimney that had already been built, as one can see from special observations in his letter, which refer to a reconstruction order by Kammler of 2 July 1942,[261] while this order was really dated 2 June. Actually, the 11,500 RM so approved concerned the cost estimate for the reconstruction of the chimney dated 3 July.

I have been unable to ascertain with certainty whether the chimney was rebuilt, even though on 29 April 1943 Bischoff informed *WVHA* about the completion (*Fertigstellung*) of the crematorium chimney (and of the shed housing the pumps for the water supply to this plant).[262] For reasons of chronology, this report could not easily have referred to a chimney that would have been built by Koehler nearly nine months earlier. Besides, there is no trace in any document for work done on such a project, and moreover, the *Bauausgabebuch* (log of building expenses) for the crematorium, which covers the period of 1st April 1942 through 31 July 1943, has entries only for payments to Koehler in connection with the chimney built in July and August of 1942, viz. 4,659.94 RM,[263] the figure which appears also in Koehler's invoice of 26 August 1942[264] as well as in their final invoice[265] and in the final settlement by the Central Construction Office dated 10 February 1943.[266]

This figure stems from Koehler's second offer of 14 July 1942, but shows a price increase, because, as we have already stated, in addition to the flue-gas channel covered by the first offer, Koehler had built a further channel, changing the total channel length from 12 to 19.5[267] meters. The pertinent addendum to the contract between the Central Construction Office and Koehler explains the details.[268]

[268] *Nachtrag zur Vertragsurkunde* dated 23 November 1942. RGVA, 502-2-23, p. 16.

After August 1942, the only reliable information I have found concerns the repair of an electric blower (*Gebläse*) on Furnace 2 on 1st September 1942 (for the blower (*Druckluftanlage*) of this furnace).[269]

In January of 1943, a *Schweizer Baracke*[270] for the Political Department[271] was erected next to the crematorium, which suggests that the chimney had at last been repaired.

It is nearly certain that the crematorium ceased its operation on 17 July 1943, in accordance with the following letter written by Bischoff the previous day and addressed to the head of SS garrison administration (*SS Standortverwaltung*), *SS Obersturmbannführer* Möckel:[272]

> *"This office informs you that the placement of the two barracks for the Political Department, the Schweizer Baracke in particular, was based on the condition that Crematorium I would cease its operation completely, as we were assured in the a.m. discussion with SS Ustuf. Grabner.*
> *Now that work on the two barracks has almost been completed, we have found that the crematorium went into operation once again.*
> *The high flammability of these structures requires that the crematorium be taken out of service; any responsibility for ensuing damage by fire must be rejected* [by this office]*."*

6.2. The Furnaces of Crematoria II and III at Birkenau

The problems concerning cremations became even more serious when construction of the Birkenau Camp was launched on 15 October 1941. For the new camp, which was originally projected to take in 125,000 Soviet PoWs – its official designation *Kriegsgefangenenlager* (*KGL* or *K.G.L.*)[273] reflects this – the Construction Office had planned for a crematorium with five furnaces of three muffles each, plus an underground morgue (*Leichenkeller*) and waste incinerator (*Müllverbrennungsofen*); but the installation was to be set up within *KL* Auschwitz (Main Camp) rather than in Birkenau;[274] for the Birkenau *KGL* only a mortuary hall (*Leichenhalle*) was planned, as we can gather from the earliest known document (7 October 1941).[275] As opposed to this, the plan for the *KGL* dated 5 January 1942 shows ten morgues and two cremation halls (*Verbrennungshallen*),[276] each of which was to be provided with one triple-muffle furnace of a simplified design.

[269] RGVA, 502-1-153, p. 5.
[270] Wooden barracks measuring 28.20 by 6.20 meters.
[271] The respective *Übergabeverhandlung* is dated 8 February 1943. RGVA, 502-2-150, pp. 7-9; cf. Mattogno 2015, Documents 13-15, pp. 78-80.
[272] RGVA, 502-1-324, p. 1; cf. Document 183.
[273] As opposed to this, the official designation for the Auschwitz Camp was *Konzentrationslager* (K.L.).
[274] *Erläuterungsbericht zum Vorentwurf für den Neubau des Kriegsgefangenenlagers der Waffen-SS, Auschwitz O/S*. RGVA, 502-1-233, p. 20.
[275] *Lageplan des Kriegsgefangenenlagers-Auschwitz O.S*. dated 7 October 1941, in: Pressac 1989, p. 185.
[276] *Lageplan des Kriegsgefangenenlagers Auschwitz Ober-Schlesien* dated 6 January 1942, in: *ibid.*, p. 189; *Lagerskizze des Vorhabens Kriegsgefangenenlager der Waffen-SS in Auschwitz. Einfriedigung* (fence). RGVA, 502-1-235, p. 13; cf. Document 184.

A "Lay-out plan of the PoW camp at Auschwitz, Upper Silesia, Plan No. 885," drawn by *SS WVHA* on 5 January 1942,[277] checked ("*geprüft*") by *SS Untersturmführer* Dejaco on 5 January and approved ("*genehmigt*") by Bischoff the following day, 6 January, does maintain in its legend the indication "*V…Verbrennungshalle*," but no longer shows the symbols representing these two installations; instead, we have a *"Krematorium"* measuring 55.50 m by 12.0 m with a chimney wing of 12 by 10 meters – the future Crematorium II (cf. Document 185). This means that the decision to move the new crematorium with its five triple-muffle furnaces from the Main Camp to the Birkenau *KGL* had already been taken in Berlin.

According to the Topf estimate of 12 February, the two furnaces initially planned for the cremation halls were priced at 14,212 RM, plus 440 RM for the chimney lining (cf. Document 228). On 27 February, when *SS Oberführer* Kammler came to Auschwitz on an inspection tour, the decicion to move the new crematorium to Birkenau was confirmed, and the order for the two triple-muffle furnaces originally to be installed there was cancelled. Topf, though, requested 1,769.36 RM as payment for the design work.[278] In order to avoid paying out this sum for no useful purpose, the Central Construction Office, with the approval of the head of Office C/III of *WVHA*, *SS Sturmbannführer* Wirtz, decided to maintain the project and to use the furnaces in a different building.[279] Topf was informed of this decision on 8 April,[280] but the company had already mailed the corresponding invoice to the Central Construction Office on 17 March.[281] As we will see, the two furnaces are mentioned for the last time in a file memo of the Central Construction Office dated 21 August 1942 (cf. Document 187), but it is not known whether they were ever set up.

The KL Auschwitz construction program for the third year of the war, drawn up after Kammler's visit on 27 February, included the installation of a "crematorium in the PoW camp" (*Krematorium im Kriegsgefangenenlager*)[282] budgeted at 403,000 RM, less than 2% of the total budget (24,254,300 RM).[283] This crematorium was the one originally planned for the *Stammlager*.

Work was assigned to the Topf Company. On 11 October 1941 the Construction Office cabled the Erfurt firm asking for Prüfer to be sent to the camp "for the new construction of a crematorium."[284] On the 14th Topf confirmed receipt of the telegram, saying that Prüfer would arrive on the 21st at 9 o'clock,

[283] Letter from *Zentralbauleitung* to WVHA dated 17 March 1942. RGVA, 502-1-319, pp. 202-206.

[284] RGVA, 502-1-313, p. 179.

which was what happened.[285] On 21 and 22 October, Prüfer, in fact, had meetings with *Bauleiter* Bischoff during which the latter gave a verbal order to Topf for: five triple-muffle furnaces with blower, two Topf draft-enhancing devices in suction for about 10,000 m³ per hour, and a waste incinerator. Delivery was to be three months and the foundations were to be poured within eight weeks. On the basis of the plans handed to Prüfer, Topf was furthermore to calculate the required height and cross-section of the chimney.[286] Referring to these meetings, Topf asked the Construction Office on 31 October for a written confirmation (*Bestätigungsschreiben*) of Bischoff's verbal order[287] and announced the forthcoming dispatch of various documents concerning the crematorium (cost estimates, drawings for the triple-muffle furnace, for the foundations, for the chimney etc.).

The first detailed description of the new crematorium is contained in a letter written by Topf on 4 November which is important enough to be quoted in its entirety:[288]

"We thank you for the order concerning
5 Topf triple-muffle incineration furnaces with blower
2 coffin-introduction devices with rail system for 5 furnaces
3 Topf draft enhancers in suction
1 Topf waste incinerator.
Flue-gas section
We accept this order on the basis of the cost estimate attached[289] *and its conditions, for a total price of 51,237 RM.*
We supply:
a) For the 5 Topf triple-muffle cremation furnaces all refractories and insulating materials, fittings of cast and wrought iron, the blowers with drives and the cost of two builders for the supervision of the work.
b) The 2 coffin-introduction devices with their mobile carts, including distribution rails for the 5 cremation furnaces.
c) The 3 Topf draft enhancers in suction including drives, and supply of a builder for installation of the devices
d) For the waste incinerator, all refractories and insulating materials, including the fittings of cast and wrought iron, and the cost of a builder for the supervision of the work. e) For the flue-gas ducts, all refractories and insulating materials, and the supply of a builder.
To be supplied by the customer:
For the furnaces and the flue ducts, all construction materials such as bricks, sand, lime and cement in the quantities to be derived from the cost estimate as well as all wrought-iron anchor bars at no cost to us.
You will, moreover, supply our builders with a sufficient number of assistants at no cost to us.

[289] I have not found this document.

Construction time of the plant as estimated by us must not exceed 8 weeks, because we have based the dispatch of our personnel on this period. If construction time were to be extended, working hours furnished must be reimbursed at daily rates.
In view of the fact that the cold season will not allow work on the furnaces to be carried on in unheated surroundings, you will ensure the rapid construction of the furnace hall and its heating.
Delivery:
We shall do our best to ensure delivery of the furnaces within the 3 months requested by you. This assumes that no delay is encountered in the supply of the materials and that no further manpower is removed [for military or other duties].
We shall require from you 6 freight bills with the necessary priorities and we ask you to let us have them as soon as possible.
Kennziffer:
We ask you to ensure that an authorization codefor 17,600 kg be assigned to us as soon as possible.
Drawings:
You will receive shortly the drawings for the preparation of the foundations of the furnaces and for the manufacture of the anchor bars.
We attach the drawing for the overall lay-out with the positioning of the furnaces, the flue-gas channels and the de-aeration section, as well as a drawing of the triple-muffle furnace.
Design:
We wish to underline that the furnace muffles are now larger than in the previous furnaces. By this, we intend to achieve a higher efficiency.[290] *For the same reason, we have included 3 draft enhancers in suction instead of 2, also taking into account that frozen corpses will have to be incinerated as well, requiring more fuel and thus increasing the spent-gas volume.*
We assure you of the supply of an installation in keeping with the state of the art, and of proper workmanship, and salute you, Heil Hitler."

Prüfer tried furthermore to make use of his increasingly influential situation at Auschwitz in order to obtain a special treatment for Ludwig Topf, one of the two co-directors of the firm, who was doing military service at the time as a *Bausoldat* in the 3rd Construction Reserve Battalion (*Bau-Ersatz-Bataillon*) stationed in Thuringia – very-probably in keeping with a request of the other co-director of the firm, Ernst Wolfgang Topf. On 12 November 1941, after a telephone conversation with a Topf employee – Prüfer, most-likely – Bauleiter Bischoff sent a letter to the Weimar *Rüstungskommando* requesting a temporary-duty assignment of three weeks for Ludwig Topf, wrongly described as a Topf project engineer (*Sachbearbeiter*), for the new crematorium-construction work which was to begin on 18 November. In this letter, Bischoff gives some interesting explanations concerning the purpose of the new crematorium:[291]

"The Topf & Söhne Co. combustion plants, of Erfurt has been ordered by this authority to build a cremation plant as quickly as possible, in view of the fact

[290] The term *Leistung* also indicates the performance.
[291] RGVA, 502-1-314, pp. 8-8a.

> *that Concentration Camp Auschwitz has been augmented by a PoW camp which is to take in some 120,000 Russians shortly. The construction of the incineration unit is most urgent, if epidemics and other risks are to be avoided."*

It appears that the leave was not granted, because on 21 November, Prüfer launched another effort by means of a letter to Bischoff, marked "strictly personal." Prüfer, who was about to go to Auschwitz, wanted to take Ludwig Topf along and have him participate in the discussions in the alleged role of a project engineer for the triple-muffle furnace.[292] For this reason, he asked Bischoff to send Topf a cable as follows:[293]

> *"Urgently requesting visit by Ludwig Topf 2-5 December for discussion new furnace construction."*

Bischoff accepted and sent Topf a telegram with this text, undated,[294] but surely transmitted on 25 November, the day on which Prüfer's letter was registered at Auschwitz. What happened after that is not known, as Ludwig Topf's name no longer appears in the correspondence between the company and the Central Construction Office.

The first drawing of the new crematorium was prepared by *SS Untersturmführer* Walter Dejaco on 24 October 1941.[295] On 20 November 1941, *HHB* sent the Central Construction Office two sketches approved by the head of Office II B,[296] in which, however, the chimney with its two smoke ducts was located in an unsuitable position. On 3 December, the Central Construction Office forwarded to the head of Office II B a drawing showing the positioning of the crematorium, the chimney, the flue ducts and the draft enhancers, pursuant to Topf's layout. In particular, it was requested to approve the central location of the chimney as a means of avoiding overly long ducts.[297]

The parts of the five triple-muffle furnaces were sent by Topf in two separate shipments: the first freight car (No. 4.62703 B.M.B.) left on 16 April 1942 with a load of 11,149 kg and arrived at Auschwitz on the 18th (cf. Document 213); the second one (No. 93413 Erfurt X) with a load of 4,948 kg followed on 18 June and arrived on the 20th (cf. Document 214). On 8 May, Topf sent the Central Construction Office the drawing for the installation of the three draft enhancers (D59389) and the drawing for the waste incinerator (D59434), which could be fed from either side.[298] During May, Topf installed at Buchenwald the first of the two triple-muffle furnaces for the local crematorium; this furnace, which was of the same type as the five triple-muffle furnaces planned for Auschwitz, could however not be started up for lack of the blower (*Gebläse*) and its motor.

---

[292] Actually, the furnace with three muffles, just like the 8-muffle furnace, was designed by Prüfer. Letter from Kurt Prüfer to Ludwig and Ernst Wolfgang Topf dated 6 December 1941. APMO, BW 30/46, p. 6.

[293] RGVA, 502-1-314, pp. 2f.

[294] RGVA, 502-1-314, p. 5.

[295] The drawing includes the façade and the elevation of the crematorium. The two drawings have been published by Pressac 1993, his Document 9.

[296] RGVA, 502-1-313, p. 68. The two sketches have been published by Pressac (1993, Documents 10f.).

[297] RGVA, 502-1-312, p. 93.

[298] Letter from Topf to *Zentralbauleitung* dated 8 May 1942. RGVA, 502-1-312, pp. 65-68.

Therefore, on 29 May, Topf asked the Auschwitz Central Construction Office to send this device to the Weimar-Buchenwald Central Construction Office by taking it from the Auschwitz parts, but Auschwitz refused: the blower was intended for the Auschwitz furnaces and would be required shortly. Topf was also told by Auschwitz that the construction of the crematorium was proceeding at "full throttle."[299] Work, in fact, had begun on 2 June[300] with the digging of the pit (*Baugrube*) for the foundations,[301] which concluded in July.[302] On 2 August, the Central Construction Office sent to the Huta Company the crematorium Drawings Nos. 936, 1173, 1174, 934, 980, 933, 1311, 932, 1301 and 1341 for the structural design of the building.[303]

By 14 August, the *Kommando Krematorium* was already 80-inmates strong.[304] On Monday, 17 August, Topf cabled the Central Construction Office that Engineer Prüfer would arrive on Wednesday, 19, at 8 o'clock.[305] In fact, at 2 PM on 19 August, Prüfer had a long meeting with *SS Untersturmführer* Fritz Ertl in the offices of the Central Construction Office, possibly in the presence of Robert Koehler, which Ertl recorded in a detailed memo (*Aktenvermerk*) on 21 August. The decisions taken at the meeting were as follows:[306]

> *"1) Mechanic Holik will arrive here from Buchenwald on 26/27 August at the latest, Builder Koch in two weeks. Erection of the 5 pcs. triple-muffle furnaces at KGL will start immediately. The Koehler Co. of Myslowitz will undertake the lining of the furnaces and the ducts as well as the erection of the chimney in accordance with the drawings and specifications of Topf & Söhne Co.*
>
> *2) Concerning the placement of 2 triple-muffle furnaces near the 'bathing facilities for special actions'*[307] *Eng. Prüfer suggested to take these furnaces from a consignment to Mogilev ready to be shipped; the* [Auschwitz] *section chief presently at* SS Wirtschafts- und Verwaltungshauptamt *in Berlin was notified of this immediately by telephone and was requested to take the necessary steps.*
>
> *3) Concerning the erection of a 2nd crematorium with 5 triple-muffle furnaces as well as aeration and de-aeration installations, results of the negotiations on assignment of materials, already under way with* Reichssicherheitshauptamt (RSHA)*, must first be waited for.*
>
> *4) Topf & Söhne Co. has by mistake sent to Auschwitz the parts of a double-muffle incineration furnace actually destined for Mauthausen. Eng. Prüfer suggests erecting this furnace here. The 2 introduction doors and the 2 ash-removal doors still missing can in the meantime be taken from the shipment of the 5 triple-muffle furnaces.*
>
> *5) The damages to the newly erected chimney for the existing crematorium* [at the Main Camp] *were inspected in the company of Herr Koehler and* SS Unter-

> scharführer *Kirschnek and measures to be taken were discussed. – As the chimney lining expands under the great heat, it must be enabled to move freely at the top and must not be attached to the outer mantle.*
> *6) On Thursday, 20 August 1942, the building site of the 5 triple-muffle furnace* [*sic*] *at KGL was inspected in the presence of* SS Strm. [Sturmmann] *Janisch and Herr Koehler, and the necessary measures were discussed.*
> *7) Eng. Prüfer requested a written order for the supply of the 2 pcs. triple-muffle furnace and the double-muffle incineration furnace, as well as to be informed soonest as to whether the furnaces of the Mogilev consignment can be diverted.*
> *8) For the supply of the fireclay and other materials still missing, Topf & Söhne Co. must immediately be supplied with 10 freight bills."*

In an effort to support his suggestions, Prüfer asked Topf to send four copies of Drawing D59599 of the triple-muffle furnace, which went out on 20 August;[308] however, as we shall see in the following section, the only suggestion accepted was the diversion to Auschwitz of two furnaces from the Mogilev consignment.

On 24 August, Robert Koehler proposed to the Central Construction Office the construction of the flue ducts, having sections of 1.20 m × 0.80 m and 0.70 m × 0.60 m respectively, on the basis of Drawing No. 932 for the sum of 3,950 RM, as well as the installation of the triple-muffle furnaces (lining and flue duct) on the basis of Drawing No. D59090, for a price of 2,100 RM per furnace.[309]

On 11 September, the Central Construction Office asked the firm Huta Hoch- und Tiefbau A.G. urgently to provide to Topf five bricklayers "for the erection of the combustion furnaces in the KGL crematorium."[310] Work on the furnaces began during that month;[311] by October, one furnace had been finished with another under way,[312] in November, two furnaces had been completed with another two under construction.[313] Work, including the flue ducts and the chimney, was finished in January of 1943.[314]

Work on the chimney ended in October of 1942 with the installation of the lightning rods, as shown by an order given by the Central Construction Office to the electricians' section on 17 October for the following job on the [future] Crematorium II: "Fabricate and install a four-part lightning rod on the chimney of Crematorium I of KGL"; the work was done between 23 and 27 October.[315]

Construction of Crematorium III began on 14 September 1942[316] with the necessary excavations (*Schachtarbeiten*);[317] initially, on 23 September, 60 detainees were assigned to this job.[318] Two days later, the Central Construction

[318] Phone call by SS *Obersturmführer* Schwarz of 22 September 1942. RGVA, 502-1-19, p. 271.

Office placed an order with Topf by telephone for five triple-muffle furnaces, three draft enhancers in suction and the necessary refractories for the flue ducts of Crematorium III. As we can see from Topf's letter of confirmation, the corpse-introduction system for these furnaces had been simplified:[319]

> *"Furthermore, for the new order, we have altered the coffin-introduction device by providing each furnace with a wrought-iron stretcher for the placement of the corpses, and with the necessary rollers on the furnace."*

This system obviously rendered the rail device superfluous. On 5 October, Topf sent the Central Construction Office Drawing No. D59389 concerning the draft enhancers for Crematoria II and III.[320] On 6 October, Topf's master bricklayer (*Polier*), Wilhelm Koch, who was working on the furnaces for Crematorium II, received permission from Bischoff to enter the Central Construction Office workshops "to check on the fabrication of anchoring parts for the *KGL* crematorium."[321]

The detainee workshop (*Häftlings-Schlosserei*) had been assigned this job on 8 September, and worked on it with 22 detainees between 9 September and 11 December 1942 for a total of 2,389 working hours, 24 of which were devoted to welding.[322]

On 26 October, the Central Construction Office informed Topf that Crematorium III would be built facing Crematorium II and would be its mirror image.[323] On the same day, the Central Construction Office confirmed to Topf in writing its verbal order of 25 September on the basis of Topf's estimate of 30 September, viz.: five furnaces of three muffles with five coffin-introduction stretchers (*Sarg-einführtragen*) for 39,150 RM, three draft enhancers in suction for 9,048 RM; the refractory materials for the flue ducts for 5,504 RM; for a total of: 53,702 Reichsmarks.[324]

On 31 October, Topf gave written confirmation of the order at the prices indicated.[325] On 28 October and at the request of the Central Construction Office dated 22 October, Topf sent to Auschwitz Drawing No. D59394 "for furnace II and III of KGL."[326] During October, the foundations of the chimney were poured, and chimney construction was begun for Crematorium III;[327] by the end of November, the chimney had reached a height of 9 meters.[328]

On 27 November, Prüfer inquired by telephone as to the priorities of the three items of the order dated 26 October and the corresponding erection work; the inquiry was repeated in writing on 30 November. The Central Construction

Office replied that it intended to give priority to the de-aeration of the old crematorium at KL, and then to the installation of the draft enhancers of Crematorium II.[329] In December of 1942, work was stopped for several days – a disinfestation and disinfection campaign had become imperative because the typhus epidemic which had broken out in early July was still ravaging the camp. As hand-over dates, under conditions of favorable weather, for the three most-advanced crematoria were projected:[330]

– Crematorium II: 31 January 1942
– Crematorium III: 31 March 1943
– Crematorium IV: 28 February 1943.

On 22 December 1942, the Central Construction Office informed Topf that Himmler had declared the above dates to be inextensible for Crematoria II and III: the Erfurt company was asked to make the necessary efforts with respect to the deliveries and the erection work. A visit by Prüfer was suggested in order to check on the progress of the project.[331] The deadlines set by Himmler were illusory, as the degree of completion of the crematoria was still low at the end of December: Crematorium II: 60%; Crematorium III: 20%; Crematorium IV: 15%; Crematorium V: 5%.[332]

Realizing this, the Central Construction Office asked *WVHA* for an extension, which Kammler granted on the condition that the work be accelerated in spite of the difficulties encountered. He also requested to be informed weekly by telegram of the degree of progress.[333] Bischoff applied Kammler's conditions to the letter and, as early as 20 November, gave a job order to the electricians' section for "Construction lighting in Crematorium II, as well as aiming of searchlights for night work / sentry chain."[334]

On 23 January the Central Construction Office placed an order with the Otto Schuler Co. of Beuel for 10 coal-hauling carts (*10 Stück Kohletransportwagen*) for Crematorium II, but the company was not in a position to supply them.[335] On 6 and 31 January 1943, Central Construction Office trucks performed four trips transporting refractories and mortar to Birkenau for the Topf project.[336] On 29 January, Prüfer inspected the worksites and wrote a report on the state of progress. The five triple-muffle furnaces of Crematorium II were being dried in ("*werden z. Zt. trockengeheizt*"), and start-up was scheduled for 15 February.

On the subject of Crematorium III, Prüfer wrote:[337]

[337] *Prüfbericht des Ing. Prüfer* to *Zentralbauleitung* dated 29 January 1943. APMO, BW 30/34, p. 101.

> *"The outer walls of the furnace building as well as the chimney have been completed. Work on the smoke ducts for the incineration furnaces will begin in 8 days. Installation of the 5 pcs. triple-muffle incineration furnaces could begin in about 5 weeks' time. Start-up for these incineration furnaces is possible on 17 April 1943 at the earliest."*

In his file memo (*Aktenvermerk*) of the same day, *SS Untersturmführer* Kirschnek, who had accompanied Prüfer during the inspection tour, added that the ceiling of the furnace hall at Crematorium III was under construction, and that the respective chimney would be ready in three days' time.[338] To make sure that everything would run on schedule, the Central Construction Office asked Topf on 2 February that Prüfer be delegated to Auschwitz for three days of each week. The Erfurt company gave its approval,[339] but it is not certain that Prüfer returned before 15 February. However, on account of various obstacles, partly caused by failures on Topf's part, work proceeded slowly, and start-up of Crematorium III was moved back to 10 April 1943.[340]

For Crematorium II, the Central Construction Office placed an order with Topf on 10 February for a coal-loading device and an ash-removal device (*Kohlenbeschickungs- und Aschentransportvorrichtung*)[341] as well as, the following day, for a waste incinerator (*Müll-Verbrennungsofen*) for Crematorium III for a total of 5,791 Reichsmarks.[342] In an effort to render Topf more responsive, the Central Construction Office meanwhile turned to Kammler, explaining the problems encountered with this company.[343] On 12 February, Topf confirmed receipt of the cable from the Central Construction Office two days earlier, and announced Prüfer's arrival at Auschwitz on the 15th, for transmittal of the proposals concerning the coal-loading and the ash-removal devices.[344] The visit probably did take place, because a Topf letter dated 26 February mentions a meeting (*Unterredung*) of Prüfer and the civilian employee Jährling on the subject of the disinfestation furnaces (*Entwesungs-Öfen*) for *BW* 32 (*Zentralsauna*). As an attachment to this letter, Topf sent to the Central Construction Office, for filing, Drawing No. D59090 of the triple-muffle furnace.[345]

According to a report by Kirschnek dated 20 February 1943, Crematorium II went into operation on 20 February 1943,[346] but it is likely that no cremations

---

[338] *Aktenvermerk* dated 29 January 1943. APMO, BW 30/34, p.105. The document bears no signature, but the registration number (*Bftgb.-Nr. 43/Ki/Lp*) shows Kirschnek's abbreviation, "Lp" is the abbreviation for the name of civilian employee Lippert, who worked at *Bauleitung* of K.G.L. "Bftgb." signifies "*Brieftagebuch*" = daily journal of correspondence.

[346] *Tätigkeitsbericht des SS-Ustuf. (F) Kirschnek, – Bauleiter für das Schutzhaftlager und für landwirtschaftliche Bauvorhaben. Zeit 1. Januar 1943 bis 31. März 1943* drawn up on 29 March 1943. RGVA, 502-1-26, p. 61.

were carried out there before the beginning of March. At that time, in fact, the painters' section of the Central Construction Office, which was covering Crematorium II with whitewash,[347] was given the job of painting black all metal parts of the cremation furnaces and of applying a coat of rust-proofing lacquer to all piping, *i.e.* very probably the compressed-air ducts leading into the furnaces. The job was completed on 27 February.[348]

Operation of the crematorium began in earnest in early March of 1943. On 2 March and on the request of the Auschwitz camp administration, *SS Obersturmbannführer* Arthur Liebehenschel, assistant head of Office Group D of *WVHA*, ordered *KL* Buchenwald to transfer immediately to Auschwitz *Kapo* August Brück[349] for work at the crematorium. (At that time August Brück was *Kapo* of the crematorium at the Buchenwald Camp.) Brück arrived at Auschwitz on 5 March.[350] The day before, *Kapo* Mieczysław Morawa, *Kapo* of Crematorium I at Auschwitz, had been transferred to Crematorium II to take on the function of *Kapo* in that facility.[351]

On 11 March, the Central Construction Office sent to the camp administration in triplicate the operating instructions for the triple-muffle furnace: two copies were to be posted in Crematorium II, a third one was filed.[352] On 17 March, Jährling wrote a memo for the file on the subject "Estimation of coke consumption at Crematorium II, *KGL*, based on data received from the Topf & Söhne Co. (builders of the furnaces) on 11 March 1943."[353] The estimate of the consumption of coke, however, refers to all four crematoria at Birkenau (see Chapter 10).

This file memo was the corrected version of a note penned by Jährling on 12 March – transmitted the same day to Bischoff and to the camp's commandant, SS Obersturmbannführer Höss – which, however, had contained two mistakes, one in the calculation of the consumption of Crematoria IV and V, the other in the sum total.[354] On 20 March, *SS Standortarzt* at Auschwitz, *SS Hauptsturmführer* Eduard Wirths, addressed a letter to the camp commandant on the subject of the detainee infirmary (*Häftlings-Krankenbau, HKB*) at *KGL* in which he requested *i.a.*:[355]

> *"For the removal of the corpses from the* HKB *to the crematorium, 2 covered hand-carts must be provided, allowing the transportation of 50 corpses each."*

At that time, on account of the enormous mortality among the detainees – more than 200 deaths per day[356] – the two crematoria already in operation (II and IV) were being used at full capacity, which immediately caused damage to them. The first problems at Crematorium II were encountered even before the official hand-over transaction of the building was concluded with the camp command (*Übergabeverhandlung*), which took place on 31 March:[357] On 25 March, Kirschnek had written a file memo on the subject of a meeting that had taken place at Auschwitz on 24 and 25 March between the Topf representatives Prüfer and Schultze and the Central Construction Office representatives, *SS Untersturmführer* Kirschnek and, most probably, the civilian employee Lehmann.[358] In this memo, Kirschnek noted with respect to Crematorium II *i.a.*:[359]

> *"As the three draft enhancers in suction have not proved to be useful in any way and have even suffered damage after the first usage at full load because of high temperatures, they will be dismantled at the expense of Topf & Söhne Co. and removed by this company."*

Central Construction Office intended to keep the three electrical motors of 15 hp each in case they were not damaged by the high temperatures and to replace the coffin-introduction carts (*Sargeinführungswagen*) by the more-practical stretchers (*Leichentragen*). On the subject of Crematorium III, Kirschnek wrote:

> *"On account of the experience at Crematorium II, the draft enhancers projected and supplied will not be mounted, but will be taken over and stored by the Central Contruction Office."*

It is clear that the problems arose a few days earlier, because Schultze and Prüfer would have had to be notified first and then travel from Erfurt to Auschwitz. The damage was due to the combined effect of two causes: in order to raise the capacity of the furnaces, the draft enhancers were run at full speed, and this, together with a mistake in the design of the triple-muffle furnace,[360] led to a rise in the flue-gas velocity such that the combustion gases generated by the corpses in the center muffles left the furnaces in an uncombusted state, with combustion taking place essentially in the flue ducts, where it caused overheating. In this manner, the three draft enhancers, placed upstream of the chimney, suffered irreparable damage. Topf could not but assume responsibility. On 16 April, they declared themselves ready to take back the three faulty draft enhancers, crediting the Central Construction Office with the sum of 3,705 RM;[361] the devices were dismantled by the Topf technician Messing between 17 and 19 May.[362]

Thus, the Birkenau crematoria operated without forced-draft devices, just like the old crematorium at the Auschwitz Main Camp after the replacement of the chimney.[363] Quite soon, however, the Central Construction Office would discover that the damage caused by the March incidents was not limited to the draft enhancers: the refractory lining of the chimney was damaged and had partly collapsed, as had parts of the vaults (*ganze Gewölbeteile*) of the flue ducts.[364] Repair work was assigned to the Koehler Co., which had built both the chimney and the ducts, whereas Topf had to redesign the damaged sections. The Erfurt company, though, possibly in an effort to avoid being once again blamed for the incidents, attempted from the beginning to stall matters.

As early as April, when Prüfer visited Auschwitz, the Central Construction Office asked Topf for a new design of the refractory lining of the chimney.[365] As Topf was dragging its feet, the Central Construction Office began to bombard the company with urgent cables; the first one, sent by SS *Untersturmführer* Kirschnek on 11 May, requested the immediate arrival of Prüfer "with all drawings and calculations of the chimneys."[366] Kirschnek used the plural "chimneys," because meanwhile the two chimneys of Crematorium IV had run into the same problems, as we can see from the urgent telegram sent by Bischoff on 14 May:[367]

> *"Bring thermotechnical and structural calculations for chimneys of Crematoria II and IV. Presence of Chief Engineer Prüfer imperative immediately."*

On the same day, civilian employee Rudolf Jährling called Topf on the telephone only to learn that Prüfer was away on a business trip to the Rhineland; he was assured that Prüfer would come to Auschwitz on 17 May,[368] but that did not happen. On 21 May, Koehler sent the Central Construction Office a letter concerning repair work on the lining of the chimney at Crematorium II. Koehler had learned from Kirschnek that Prüfer would not bring the design plans for the new project before the middle of the following week. To gain time, he proposed to dismantle the remaining parts of the chimney lining so that two of his specialists could begin with the repair work as soon as the design plans for the new project arrived. Before sending his men, he wanted to receive the order from the Central Construction Office,[369] which was issued on 29 May.

Prüfer actually did go to Auschwitz very briefly on 24 May, although not in order to bring the new drawings for the chimney lining, but to request payment of some outstanding invoices.[370] In the meantime, Topf sought to evade their responsibilities by claiming that they had not been given the order for the construction of the chimney, which had instead been placed with the Koehler Co.,

making Koehler the only party responsible.[371] This was only partly true, however, because Koehler had built the chimney on the basis of Topf's specifications, and Topf had also carried out the necessary thermo-technical calculations. Following Koehler's advice, the Central Construction Office embarked on the preliminary repair work. An undated sketch, certainly dating from that period, shows the damaged parts of the chimney.[372]

On 29 May, Bischoff cabled Topf that the drawings promised by Prüfer had not yet been received, and requested their immediate dispatch, otherwise the work would have to be interrupted. The next day Bischoff reiterated his request in another urgent telegram, and stated that the work would be interrupted that day "wegen Fehlen der Zeichnung". Topf explained that Koehler had mailed to them the original drawing and the structural calculations ten days earlier but had recalled them immediately; Topf thus had sent them back. On 29 May, Koehler had asked Topf for the preparation of a new drawing and new structural calculations, but in order to do this, Topf required the old drawing and calculations, which meant that the new drawing could only be prepared once those documents were received.[373]

On 19 June, Bischoff decided to clarify once and for all the responsibility for the chimney damage at Crematorium II. He sent Topf a letter in which he expressed his point of view quite explicitly: the previous exchange of letters and telegrams had raised the suspicion that Topf wanted to bury the whole matter. Already on the occasion of Prüfer's previous visit to Auschwitz in April, the Central Construction Office had asked him for a new design of the chimney lining, because the former one had turned out to be faulty under practical conditions. The negotiations between Robert Koehler and Prüfer had ended with the latter's promise that he would send the new design as soon as possible.

> *"Herr Prüfer knew that the former chimney installation was executed by the Koehler Company exactly in accordance with the drawing provided by you (for the development of the project, your company at the time charged 1,769.36 RM) and with the fireclay lining specified by you in your cost estimate dated 12.2.42, Item II. In spite of this, your company asked Herr Koehler in Myslowitz for a drawing and the structural calculations of the chimney, which you did receive in the end."*

Instead of coming up with a new design, Topf continued to stall for unknown reasons. "Since the facility, which was still being needed most-urgently, could not be used without the completion of the new chimney lining," Bischoff asked Topf to keep its word and to send the new design to the Koehler Co. immediately.[374]

Finally, Topf sent the requested documents. On 19 July, the Central Construction Office informed Topf that "the subject work was nearly finished" and placed the responsibility squarely on the Erfurt company:[375]

[371] Letter from Topf to *Zentralbauleitung* dated 25 May 1943. RGVA, 502-1-313, pp. 36-36a.
[372] APMO, BW 30/34, p. 24.
[373] Letter from Topf to *Zentralbauleitung* dated 2 June 1943. RGVA, 502-2-54, pp. 87-87a.
[374] Letter from *Zentralbauleitung* to Topf dated 19 June 1943. APMO, BW30/34, pp. 22f.
[375] Letter from *Zentralbauleitung* to Topf dated 17 July 1943. APMO, BW 30/34, p. 17.

> *"On the basis of the new drawings supplied by you one can see that your initial design of the chimney did not take into account the differences in the thermal expansions and the high temperatures to be expected and that this was taken into consideration only in your second design. The question of responsibility is thus unresolved until we receive respective instructions from our superiors in Berlin. We advise you furthermore that the very-seriously affected heating channels (on various occasions complete sections of the vaults collapsed) will have to be repaired and/or rebuilt shortly."*

In their long reply to this letter, Topf reiterated that they had nothing to do with the construction of the chimney, for which they had specified merely the height and the cross-sectional area, and insinuated that Koehler Co. might have used bricks of poor quality and ordinary mortar instead of clinkers and refractory mortar. Moreover, Topf knew nothing of the damage to the flue ducts:[376]

> *"Our supervisor Koch who returned from your site 3 weeks ago did not report any such damage, although he had once again checked everything before leaving. As the crematorium has been out of service for 6 weeks, we cannot explain who has caused the alleged collapse of the ducts."*

On 10 September 1943, Prüfer visited the Central Construction Office to discuss with Bischoff and Kirschnek the liability for the chimney damage and the expenses involved. The following day, Robert Koehler was summoned as well. *SS Untersturmführer* Kirschnek wrote a long account of the discussions on 13 September,[377] which, however, was full of mistakes and was not approved by Bischoff and had to be redrafted the day after.[378] This document, which we summarize here, sets out the positions of the three parties involved. The Central Construction Office asserted that the damage to the chimney was primarily due to mistakes in the design and to poor advice from Topf on the subject of the construction.

In 1942, Prüfer had been the consultant for the entire installation, and had declared to members of the Central Construction Office that the crematoria had to be built in accordance with the drawings provided by Topf. As far as the chimneys (of Crematoria II and III) were concerned, they had, on the one hand, been erected in accordance with the specifications of the chimney originally to be built at the *Stammlager* and, on the other hand, the dimensions and structural details had been taken from Topf drawings. The original drawings showed a refractory lining 12 cm in thickness up to a height of 6 meters; above this level, there were ordinary bricks. The Central Construction Office insisted, moreover, on the correctness of the information concerning the partial breakdown of the flue ducts which Topf had put in doubt: these facts had been ascertained by the *Ober-Kapo* of the crematoria.

> *"On this occasion – Kirschnek goes on to say – it was also observed that all* [flue-duct] *dampers controlling the draft had melted on account of their wrong*

> *installation; the problems were resolved on the basis of* [our] *own experience and currently permit flawless operation."*

Prüfer, for his part, brought in a new explanation which again blamed the Koehler Co.: the damage was due to the fact that, above 6 m, ordinary mortar instead of refractory mortar had been used, and also because of mistakes in the structural calculations of the chimney, but this was denied by Robert Koehler, who was questioned on this point the following day. The Central Construction Office could not but reproach Prüfer for giving a different reason on each of his visits to Auschwitz.

> *"On his last visit but one he named, in the presence of the commandant, the great stresses due to the firing of single furnaces – something not considered in the design – to have been the cause."*

The Central Construction Office agreed with this explanation, all the more-so as Topf's new design for the chimney lining contained a number of open gaps, "so that the expansion of the brickwork relative to that of the lining can absorb possible stresses caused by the firing of single furnaces."

Robert Koehler's case rested on the overloading of the chimney. In the end, a compromise was reached which terminated the controversy for good: each of the parties involved – Topf, Robert Koehler, the Central Construction Office – would pay one third of the cost of the repair work, estimated to be 5,000 RM,[378] but actually only amounting to 4,500 RM when the job was finished. Topf confirmed Prüfer's decision on 16 September, reluctantly accepting to pay its share.[379] On 28 September the Central Construction Office reminded Robert Koehler of his obligation, and informed him that he would receive the corresponding invoice in a few days.[380] Topf was sent their own invoice – in the amount of 1,621.30 RM – a day later.[381]

Summarizing matters, the damage to the chimney and the flue ducts occurred in the latter half of March but was discovered only in the following month,[382] as the Central Construction Office requested Prüfer to send a new design for the chimney lining at that time. Work on the dismantling of the damaged refractory lining began a few days after the arrival of Robert Koehler's letter of 21 May, probably on 24 May, after Bischoff's telephone conversation with Prüfer; it stopped on 1st June, but it was not possible to carry out further repairs, because the new design of the chimney lining had not yet been received. This repair project was assigned to the Koehler Co., whose personnel were surely present at Auschwitz on 29 May, and it is probable that Koehler took part in the dismantling job.

In the Topf letter of 23 July, it is said that Crematorium II had been out of service for six weeks, *i.e.* since 11 June, but any cremation activity surely ended

---

379 Letter from Topf to *Zentralbauleitung* dated 19 September 1943. RGVA, 502-1-313, p. 16.

380 Letter from *Zentralbauleitung* to Koehler Co. dated 28 September 1943. APMO, BW 30/34, p. 16.

381 Letter from *Zentralbauleitung* to Topf dated 29 September 1943. APMO, DZ-Bau, nr. inw. 1967, p. 183.

382 Inspection of the flue-gas ducts and of the base of the chimney was possible earlier, because each of the five ducts was equipped with an inspection hole 45 cm × 51 cm closed by a double lid (*Fuchseinsteigeschachtverschluss. Rahmen* [frame] *mit Doppeldeckel*), while the chimney possessed a cleaning port 39 cm × 51 cm with closure *(Reinigungstür*).

earlier than that, because one cannot imagine any cremations being carried out with workers present inside the chimney; hence, cremations must have stopped around 24 May.

The crematorium was possibly used normally until the damage was discovered, but, keeping in mind the Central Construction Office's experience with the Main Camp Crematorium, it is difficult to believe that operation would have been at full load later on; in fact, between 24 and 30 April 1943 all windows of the furnace hall of Crematorium II as well as those of the adjoining rooms were being blackened[383] (a countermeasure against air raids). Repair work on the chimney lining began after 19 June – when Koehler had not yet received Prüfer's new design – and was essentially concluded on 17 July 1943, but it was still necessary to repair the flue ducts. The repair work on the flue ducts probably ended only in late August, because on 30 August the Central Construction Office asked the materials store (*Materialverwaltung*) for the supply to Crematorium II of various lacquer products for use by the inmate paint shop (*Häftlings-Malerei*).[384]

At the end of March 1943, the construction of the cremation furnaces had hardly begun on Crematorium III.[385] Even though the Central Construction Office attempted to speed matters up – for the first two days of May it asked the camp command that the *Kommando Krematorium* be increased to 250 detainees for urgent tasks[386] – work dragged on well beyond the target date of 10 April 1943. The hand-over transaction, in fact, bears the date of 24 June 1943,[387] and that is probably also the start-up date, because the lightning rods of the chimney were installed on 21 and 22 June.[388] On 28 June, the Central Construction Office reported to *WVHA* the completion of Crematorium III. This letter begins with the following words (cf. Documents 248, 248a):

"I announce completion of Crematorium III as of 26 June 1943."

This is followed by the report of the "throughput" (*Leistung*) of the four existing crematoria "for an operating time of 24 hours": 340 "persons" (*Personen*) for Crematorium I (six muffles), 1,440 "persons" for each of Crematoria II and III (fifteen muffles each), 768 "persons" for each of Crematoria IV and V (eight muffles each); for a total of 4,756 "persons." Concerning the data given in this letter – absolutely incredible from a technical point of view (coke consumption

and duration of the cremation) – we refer the reader to Chapters 8-10, in particular to Subchapter 9.6.

On 20 August 1943 the Plützsch Co. sent to Auschwitz on Topf's orders a freight car with 3,750 normal refractory bricks, 400 conical refractory bricks and 1,500 kg of refractory mortar, but the *Materialverwaltung* (materials administration) did not credit the shipment to Topf "because the work had not yet been finished." Consequently, the Central Construction Office, believing that they had paid for the materials out of their own pocket, sent Topf the corresponding invoice in an amount of 887.95 Reichsmarks. Topf, on 7 December, suspecting a mistake, asked the Central Construction Office to check into the matter; on 16 December the mistake was rectified.[389]

The work referred to by the *Materialverwaltung* did not, however, concern the crematoria, but the two hot-air-disinfestation chambers to be installed in the *Zentralsauna*.

The first damage to the cremation furnaces themselves arose at the end of October of 1943. On 27 October, the Central Construction Office ordered the metal-working shop at *DAW*[390] to repair 20 ash-removal doors. Work was finished on 27 January 1944.[391]

On 22 November, the garrison administration asked the Central Construction Office for the "installation of heating stoves in the crematoria constructed, as well as erection of a roof over the refuse pit near Crematorium II."[392] A month later, *SS Untersturmführer* Josef Janisch, *Bauleiter* at *KGL*, replied that "the stoves needed in the detainee housing area of Crematorium II have been installed,"[393] which suggests at least the imminent transfer of the detainees working at Crematorium II into the lodgings arranged for them in the attic of the building.

On 30 January 1944, the Central Construction Office sent Topf a telegram asking Prüfer and the mechanic Koch to come to Auschwitz immediately to repair the walls of the hot-air chambers of the disinfestation facility set up at the *Zentralsauna*. Topf accepted (albeit sending foreman Holick rather than Koch),[394] and on 2 February 1944, the Central Construction Office requested the camp commandant *SS Obersturmbannführer* Liebehenschel, to issue a camp-access permit for the two men, giving the following reason:[395]

> *"Senior Engineer Prüfer and Herr Holick have been called here by this authority to inspect and/or repair the damage detected at the large disinfestation unit of* KGL *and at the crematoria."*

[394] Letter from Topf to *Zentralbauleitung* dated 9 February 1944. RGVA, 502-1-336, pp. 88-88a.

[395] Letter from *Zentralbauleitung* to *SS-Obersturmbannführer* Liebehenschel dated 2 February 1944. RGVA 502-1-345, p. 50.

Damage to the disinfestation furnaces was less-serious than had been feared: only the joints between the heating channels and the brickwork had opened up, and Holick would close them up with Monolite mortar,[396] a refractory material. Damage to the crematoria furnaces, however, was more-serious. On 22 February, the garrison administration ordered the Central Construction Office to supply 20 sacks of Monolite, 200 refractory bricks and 200 refractory wedge bricks for "imminent repairs on the crematoria."[397]

On 13 April 1944, the Central Construction Office ordered *Schlosserei* of *DAW* to repair 20 furnace doors and 10 scrapers at Crematoria II and III. The job was completed on 17 October 1944.[398] In early May, damage to the brickwork was reported, certainly in the flue ducts or the chimneys, because on 9 May the *Bauleiter* of *KL* II (Birkenau) asked the camp command for a "permit for entry to Crematoria I-IV" to be issued for Koehler Co., because the firm had been contracted to execute "urgent repairs on [the] crematoria."[399]

At the end of the month, more damage struck the furnaces. On 31 May, the Crematoria Administration at Birkenau ordered *DAW* to repair two muffle doors and five closures,[400] plus other minor jobs. The repair work was done between 20 June and 20 July and cost 46.90 RM (Czech 1989, p. 789). A later order, dated 7 June 1944, concerned "required repairs on Crematoria 1-4 between 8 June and 20 July 1944." Work was reported completed on 6 September 1944.[398]

Operation of Crematoria II and III ceased in early December of 1944: On 1st December, a women's detail was set up for the demolition of Crematorium III (Czech 1989, p. 939); on the 8th, the head of the Central Construction Office, *SS Obersturmführer* Jothann, asked *Abteilung* IIIa (assignment of detainees) to assign immediately 100 detainees for demolition work "near crematorium camp II),[401] undoubtedly meaning Crematorium II.

On 20 December 1941, Topf sent to Auschwitz a preliminary invoice, dated 18 December, in accordance with its cost estimate of 4 November, of which only the first page has been preserved: the five triple-muffle furnaces cost 6,378 RM each, the coffin-introduction devices 1,780 RM, the complete flue ducts 4,045 RM, and the three draft enhancers 3,016 RM each.[402] These amounts are in agreement with those appearing in Topf's Invoice No. 69 of 27 January 1943[403] and in the final invoice bearing the same date.[404] Besides the items mentioned above, these invoices also comprise a waste incinerator at an amount of 4,474 Reichsmarks.

403 Topf, *Rechnung Nr. 69* dated 21 January 1943 concerning the construction of 5 triple-muffle furnaces at Crematorium II. RGVA, 502-1-327, pp. 100-100a.
404 Topf, *Schluss-Rechnung* dated 27 January 1943 concerning the construction of 5 triple-muffle furnaces at Crematorium II. RGVA, 502-2-26, pp. 230-230a. Cf. Document 215.

The total cost of the devices supplied and installed by the Topf Company thus came to 51,237 Reichsmarks. From this figure, 3,705 RM were deducted as reimbursement of the three draft enhancers taken back by Topf after they had been damaged. The remaining 47,532 RM were paid by *Kasse der Bauinspektion der Waffen-SS und Polizei Reich-"Ost"* in two advance installments of 25,000 RM on 13 February 1942 and of 15,000 RM on 17 September, and a final amount of 7,532 RM on 22 November 1943.[405]

The total cost of the devices supplied by the Topf Company and installed in Crematorium III was 53,702 RM: 39,150 for the five triple-muffle furnaces (costing 7,830 RM each), 9,048 RM for the three draft enhancers mentioned in the invoice in accordance with the cost estimate of 30 September 1942, actually supplied by Topf but never installed by the Central Construction Office, 5,504 RM for the supervision of the construction work of the flue ducts.[406] Payment was effected by an installment of 27,000 RM on 4 December 1942, a second payment of 5,500 RM on 8 December 1942, and a final payment of 21,202 RM on 22 November 1943.[407]

6.3. The Furnaces of Crematoria IV and V at Birkenau

On 4 December 1941, *HHB* in Berlin ordered from Topf "4 pcs. Topf double-4-muffle incineration furnaces," *i.e.* four furnaces with eight muffles for Mogilev in Russia,[408] where PoW Transit Camp No. 185 was located. Topf confirmed receipt of the order on 9 December, but on 30 December only one half of a furnace was sent to Mogilev, *i.e.* four muffles; as we will see, two furnaces would be set up at Auschwitz while one and a half furnaces were temporarily held in Topf's warehouse.[409]

Accepting the suggestion made by Prüfer when he visited Auschwitz on 19 August 1942, *WVHA* decided on 26 August to send to Auschwitz two of the furnaces on order for Mogilew. The Central Construction Office went to work immediately. A telegram went out to Topf the same day requesting the drawing of the building meant to house for the 8-muffle furnace (the future Crematorium IV), because construction work was to begin immediately.[410] For 31 August, Topf provided the Monteur Martin Holick,[411] who also brought with him the necessary plans (D60125).[412]

For the 8-muffle furnace, Topf had designed two chimneys, each 16 m high with internal cross-sectional dimensions of 0.80 m × 0.80 m, and refractory lin-

ing up to a height of six meters. As these furnaces had originally been destined for Mogilev, where coke supply was difficult, they were equipped with hearths for wood, which Topf, for the furnaces going to Auschwitz, adapted for use with coke by means of inclined and horizontal grates: two gasifiers were equipped with horizontal grates only; the other two had inclined hearth bars changed to horizontal grates. In view of the extremely short service life expected for the inclined hearth bars, Topf recommended to the Central Construction Office to order spare coke-hearth bars. Furthermore, because of transportation problems, the Mogilev Furnaces had been designed without insulation, but Topf was ready to furnish insulating material to the Central Construction Office on request.[412] On 1st September, the Central Construction Office sent Topf 20 freight bills for the shipment of the furnaces and the refractory material.[413]

On 4 September, Topf sent the Central Construction Office the drawing of the furnace foundations (D59555) and the drawing of the anchoring system (D60129),[414] plus a list of the individual anchor bars,[415] which would be fabricated locally by the detainee workshop for the Central Construction Office.[416] On 7 September, the furnace drawing itself (D60132) was ready. In the letter of transmittal, Topf explained to the Central Construction Office that one gasifier had been allocated to each pair of muffles; the furnace thus had eight muffles and four gasifiers, which were positioned in the central part of the furnace; two pairs of muffles would be given a common chimney having the dimensions previously indicated in Topf's letter dated 31 August 1942. Topf also announced the arrival of Builder Wilhelm Koch within a week.[417]

The following day, Topf dispatched a freight car containing the metal parts of the two furnaces with a total weight of 12,186 kg, which arrived at Auschwitz on the 11th.[418] In accordance with Topf's offer of 2 September concerning the changes in the type of fuel and the corresponding modifications, the Central Construction Office ordered on 15 September four wrought-iron covers for the hearths with frames, jackscrews and refractory lining, as well as 2,500 insulating bricks and 600 kg of rock wool for each of the furnace's insulation, plus the replacement bars for the hearths of the gasifiers, at a total price of 3,258 Reichsmarks.[419] As the two furnaces had altogether eight gasifiers, there were eight covers and not four, as Topf was quick to rectify.[420] However, the respective invoice paid on 2 February 1944 still spoke of four covers – probably for reasons of accounting.[421] On 26 October, referring to the *WVHA* letter addressed to Topf on 26 August, the Central Construction Office transmitted to the Erfurt company the post-dated confirmation of the order for two furnaces with eight

muffles as per Drawing D60125, and for the technical modifications resulting from the change of the fuel type.[422] The next day, the Central Construction Office sent Topf a telegram inquiring as to the cost of an 8-muffle furnace designed for Mogilev, with anchoring and hearths for wood firing. Topf replied the same day by telegram quoting a price of 13,800 RM for the furnace.[423] Believing that the Central Construction Office wanted to order another wood-fired 8-muffle furnace, Topf tendered a quotation for such a device on 29 October. The error was soon corrected, though: the Central Construction Office only wanted a cost estimate for a furnace of the Mogilev Type for purely administrative reasons. Topf took this into account, and attached to their explanatory letter[424] a quotation for an 8-muffle furnace without anchoring (because the anchoring parts would come from the detainee workshop at Auschwitz) and with wood-fired gasifiers (because the modification of the fuel system was covered by a different contract).[425] The Central Construction Office transmitted the quotation to the *WVHA* for approval of the order.[426]

Other misunderstandings arose later with respect to payment for the two 8-muffle furnaces. On 5 April 1943, Topf drew up the respective invoice for a total of 27,632.30 RM (27,600 RM for the furnaces plus 32.30 RM for transportation).[427] On 2 June, the head of *Gruppe C/Bauwesen* of Higher SS and Police Leader Central Russia notified the Construction Inspectorate of the Waffen SS and Police East Germany (*Bauinspektion der Waffen-SS und Polizei Reich-Ost*), to which the Central Construction Office was attached, that the Construction Inspectorate Central Russia had already paid 42,600 RM for the four furnaces originally ordered for Mogilev.[428] When the Central Construction Office learned about this, it not only felt that Topf's invoice of 5 April 1943 was unfounded, but also that the Erfurt company had received (42,600 – 27,632.30 =) 14,967.70 RM more than it should have. Furthermore, the SS did not see why the invoice of 5 April 1943 amounted to 27,600 RM (plus 32.30 RM for shipment) or 13,800 RM per furnace, whereas the cost estimate of 16 November 1942 spoke only of 12,972 RM for one furnace.[429]

Topf replied that *Reichsführer-SS* had ordered four 8-muffle furnaces for a total price of 55,200 RM on 4 December 1941; moreover, as the SS had requested various modifications in the design of the 8-muffle furnace, Topf had applied a price increase of 6% or 828 RM, thus yielding a final cost of 13,800 Reichsmarks.[430] Of the four furnaces ordered, one half of one furnace (four

[429] Letter from *Zentralbauleitung* to Topf dated 2 July 1943. APMO, D-Z/Bau, nr. inw. 1967, p. 170.

[430] Actually, 828 RM represents 6% of 13,800 RM and not of 12,792; 6% of this latter figure would be 778.32 RM, and a furnace should have cost 13,750.32 Reichsmarks.

muffles) had gone to Mogilev, two were at Auschwitz, and the remaining furnace-and-a-half was still being held in the Topf warehouse at the disposition of *Reichsführer-SS*.[431]

At Auschwitz the matter was definitely clarified by civilian Employee Jährling, who made two hand-written entries on a copy of the letter from the Construction Inspectorate Central Russia, dated 2 June 1943, which the Central Construction Office had received. The first entry dates from 31 January, the second from 21 February 1944; Jährling summarizes the questions of payment from the administrative point of view: the SS had ordered four 8-muffle furnaces for a total price of 55,200 RM; the Construction Inspectorate Central Russia had already paid Topf on account 42,600 RM, to which the SS garrison administration Auschwitz had added another 10,000 RM on account,[432] which meant that Topf was still entitled to 2,600 RM.[433]

For all intents and purposes, the remaining furnace-and-a-half, still held by Topf, was the property of *Reichsführer-SS*; Jährling's computation was therefore correct, and Topf received only what it was still owed. The Construction Inspectorate Central Russia was late to be informed, because on 11 August 1944 this office once again asked the Central Construction Office whether the 42,600 RM already paid to Topf would be deducted from the final payment.[434]

In line with Topf's letter of 7 July 1943, the remaining furnace-and-a-half were taken over by *WVHA*. On 16 August, the *SS-Wirtschafter* (business manager) at Higher SS and Police Leader (*Höherer SS- und Polizeiführer*) of the Government General sent a note to the Central Construction Offices at Heidelager, Krakow, Lemberg, Lublin and Warsaw, as well as to the New Construction Office at Radom, explaining that Office CIII held "a cremation furnace and a half = 12 muffles" and asked to be informed by 1st September whether the above offices had any use for it.[435]

We know of a reply by the *Bauleiter* of Trawniki, a subcamp of Lublin (Majdanek) who, on 2 September, wrote to the Central Construction Office of the Main Camp – which had sent him a copy of the note of the SS business manager – the following letter:[436]

> *"No crematorium exists at this camp. Many protests have been raised against this situation. Construction of a crematorium would, however, be an urgent necessity. Of course, should the furnace and half available at Office C III be taken into consideration for Trawniki, this would have to be decided there* [by the Lublin Central Construction Office]*."*

I found no evidence that this request was responded to.

Little is known about the construction and the operation of the two 8-muffle furnaces of Crematoria IV and V. Construction of Crematorium IV began officially on 9 October 1942,[437] but Huta Co. had already embarked on preparatory work on 23 September.[438] The facility was handed over to the camp administration on 19 March 1943.[439] Construction of Crematorium V began on 20 November 1942;[440] hand-over to the camp administration occurred on 4 April 1943.[441]

After a few weeks of operation, the furnace at Crematorium IV began to show cracks, as the Central Construction Office informed Topf on 3 April; Topf agreed to carry out the repairs free of charge, as the warranty of two months had not yet expired.[442] Damage was undoubtedly more serious, however, because in the telegram of 14 May 1943 mentioned above, the Central Construction Office urgently requested Topf to make thermal and structural calculations for the chimneys at Crematorium IV as well.

More repair work on Crematorium IV was carried out between 1 and 7 June 1944 (30 doors and/or closures of the furnaces),[443] and between 7 June and 4 July 1944, repair work was carried out on all four crematoria.[443] Crematorium IV was rendered unserviceable in the so-called revolt of *Sonderkommando* on 7 October 1944; the service personnel (down to 53 men from 169) were only withdrawn on the 10th,[444] however. On that date, the manpower at Crematorium V was also brought down, from 156 to 66 detainees.[444] On 16 January 1945, Crematorium V was still in service with a workforce of 30 detainees.[445] It was blown up by the camp SS guards just before the arrival of the Soviets.[446]

7. Structure and Operation of the Topf Cremation Furnaces at Auschwitz-Birkenau

7.1. The Coke-Fired Double-Muffle Furnace Auschwitz Type

Topf Co. built four furnaces of this type, three of which were set up in Crematorium I or the old crematorium at Auschwitz, with a fourth one built in the Mauthausen Crematorium.

[445] *KL Birkenau, Arbeitseinsatz für den 16. Januar 1945*. RGVA, 502-1-67, p. 17a.

[446] In the aerial photo of 19 February 1945, Crematorium V appears to have been entirely destroyed. National Archives, Washington, GX 12337, exp. 145.

The Mauthausen Furnace was ordered from Topf on 16 October 1941, but the New Construction Office of *KL* Mauthausen hesitated for a long time before installing it. The parts of the furnace were shipped to Mauthausen between 6 February 1942 and 12 January 1943,[447] but only at the end of 1944 was it decided to erect it. A letter from Topf dated 20 December 1944 tells us that preparations were going on in the crematorium concerning the foundations of the furnace and the flue duct; Topf was waiting for this work to be finished before sending one of its builders.[448] On 3 January 1945, Topf announced the arrival of the technician, Chief Engineer Schulze, scheduled for 9 January.[449] The furnace was therefore built in January/February of 1945, which explains the fact that it has been preserved rather well. This furnace has remained practically intact and can be examined *in situ*.

As opposed to this, the two coke-fired Topf double-muffle cremation furnaces which are presently shown in Crematorium I at Auschwitz were refabricate by the Poles after the war in a haphazard way, with original parts taken from the furnaces dismantled by the SS in 1944. It is therefore useless to examine these refabrications in an effort to understand the structure or the operation of this type of furnace. Our technical description will hence be based on the Mauthausen Furnace. It will be illustrated by 35 photos of our own and will take into account the available documents concerning the furnaces at Auschwitz and Mauthausen which were of the same type. In fact, a letter from Topf to the Mauthausen Camp says in this respect:[450]

> *"We wish to underline that* KL *Auschwitz in Upper Silesia has just ordered from us a second coke-fired double-muffle furnace of the same design as intended for you."*

Furthermore, the "order slip" sent by the Mauthausen New Construction Office to Topf on 16 October 1941 refers explicitly to a "double-muffle furnace, Auschwitz type."[451] Furthermore, the Topf letter dated 1st November 1940 had as an attachment the Topf Drawing No. D57253 (Document 202), which is exactly the design used for the first double-muffle furnace set up at the Auschwitz Crematorium. Another attachment to the letter was Drawing No. D58173, which we have studied in the preceding chapter (Document 163).[452] We will show, first of all, the Topf cost estimate for *KL* Auschwitz dated 13 November 1940 (Document 193), which is practically identical with the one for Mauthausen dated 6 January 1941 (Document 164):[453]

"Quotation

Our Department: D/Prf.
Offer No. 40/999
House Phone No. 123
Date: 13 Nov. 40

Reichsführer SS,
Head of German Police,
Main Office Budget and Construction,
New Construction Office KL Auschwitz,
Auschwitz /Upper Silesia

Subject: 1 coke-fired Topf double-muffle cremation furnace with blower
Prepared by head engineer Prüfer!
Prep.: Prf/Hes.

#	Description	
1	*coke-fired Topf double-muffle furnace with blower including the following services and parts* *The foundations of the furnace and of the flue duct must be provided by the customer in accordance with our specifications, at no cost to us.* *Bricks, sand, lime and cement of the outer brickwork. The best bricks will be selected for the facing of the furnace.* *The necessary refractory materials consisting of normal and wedge-shaped bricks, Monolite packing and the corresponding mortar.* *For the insulation of the furnace, bricks of diatomaceous earth, rock wool and the necessary diatomaceous-earth mortar.* *Wrought-iron anchoring bars, with T, U and angled sections, tightening rods, bolts and nuts.* *Coke-fired Topf double-muffle furnace with blower including the following services and parts* *The foundations of the furnace and of the flue duct must be provided by the customer in accordance with our specifications, at no cost to us.* *Bricks, sand, lime and cement of the outer brickwork. The best bricks will be selected for the facing of the furnace.* *The necessary refractory materials consisting of normal and wedge-shaped bricks, monolite tamping mass and the corresponding mortar.* *For the insulation of the furnace, bricks of diatomaceous earth, rock wool and the necessary diatomaceous-earth mortar.* *Wrought-iron anchoring bars, with T, U and angled sections, tightening rods, bolts and nuts.* *Cast- and wrought-iron fittings such as:*	
2	*Cast-iron introduction doors with cast-iron frames. The doors will have Monolite cladding on the inside.*	

6	*Cast-iron closures for the air channels.*	
4	*Cast-iron ash-extraction doors.*	
2	*Cast iron loading doors for the gasifiers.*	
2	*Wrought-iron ash receptacles.*	
2	*Wrought-iron frames for the flue-duct dampers, lined with Monolite, including pulleys, cables and counterweights, the necessary stokers.*	
2	*Cast-iron hearth covers.*	
2	*Horizontal grates.*	
1	*Blower device consisting of a blower with its 3-phase directly coupled 1.5-hp motor and the necessary conduits.*	
	<u>Installation of the furnace</u>	
	Presence of a builder for the construction of the furnace, including travel expenses, daily rates as well as social-security contributions.	
1	*Corpse-introduction system, wrought iron, consisting of a mobile wrought-iron cart with the necessary rails.*	
	Free delivery to Auschwitz/Upper Silesia	
	Price of the furnace:	*RM 7,753*
	Weight for authorization code: 2,600 kg of iron.	
	During construction, our builder must be supplied with two assistants at no cost to us."	

Beside the offer dated 6 January 1941, we have three more estimates for the coke-fired double-muffle furnace sent by Topf to Mauthausen, dated 1st November 1940, 30 April and 31st October 1941 (Documents 194-196) which differ only in the prices and the weights of the metal parts.

Document 197, translated here, lists the elements of the second cremation furnace for KL Auschwitz, shipped by Topf on 17 January 1941:[454]

The second furnace included, moreover, a case of custom-shaped refractory bricks (305 by 250 by 60 mm, net weight 16.5 kg) which Topf shipped on 20 December 1940,[455] 50 bags of mortar mixture shipped a day later[456] as well as two cement counter-weights with eyelet holes which went out on 21 January 1942,[457] similar to those shown in Photo 172 which were used to move the dampers of the flue duct.

The cost estimate of the third furnace, dated 25 September 1941 (Document 198) is practically the same as the one dated 13 November 1940 concerning the

[456] RGVA, 502-1-327, p. 204.
[457] RGVA, 502-1-327, p. 200.

second furnace; the only differences are the price (7,332 instead of 7,753 RM), the weight of the metal parts (2,870 instead of 2,100 kg) and the mention of a rotatable platform (*Drehscheibe*).

The bill of lading of 21 October 1941 (Document 199), translated here, refers also to the third furnace:[458]

The final invoice (*Schluss-Rechnung*) for the third furnace (Document 200) not only lists the parts supplied by Topf to the Central Construction Office, but also shows the on-account made by the cashier of *Bauinspektion der Waffen-SS und Polizei Reich “Ost”* and the credit granted by the company on 13 July 1942. In accordance with normal practice, the invoice has the date of the preceding partial invoice (*Teil-Rechnung*), dated 16 December 1941, but was itself established in early June of 1942:[459]

#	*Object*	
	concerning: *Supply and erection of a Topf coke-fired double-muffle incineration furnace without foundations or smoke channel, viz:* *Supply of bricks and mortar materials for the brick mantle, the necessary fireclay materials, Monolite tamping mass, bricks of diatomaceous earth, diatomaceous mortar and slag wool for the insulation of the furnace, wrought-iron anchoring, cast- and wrought-iron doors, as well as compressed-air unit consisting of compressed-air blower with 3-phase motor and the necessary conduits.* *Dispatch of a builder including his travel expenses, daily rates and social-security contributions for the construction of the furnace.* *Supply of wrought-iron corpse-introduction device consisting of coffin-introduction cart, shoving cart, rails and rotary plate.* *In other respects in accordance with our cost estimate of 25 September 1941 and our order confirmation of 25 September 1941.*	*7,332*
	Cost of transportation for the steel parts loaded at Erfurt as per freight bill of 21 October 1941	*186.10*
		7,518.10
	– payment on account of 31 January 1942	*3,650.--*
		3,868.10

[459] Topf *Schluss-Rechnung* of July 1942 backdated to 16 December 1941 concerning the third Topf coke-fired double-muffle furnace for Crematorium I at Auschwitz. RGVA, 502-2-23, pp. 261-261a.

	– credit for rotatable platform not supplied	*82.--*
		3,786.10
	Our order no. 41 D1980 *Our invoice no. 2363*	
	To: Reichsführer-SS *and head of German police* *Hauptamt Haushalt und Bauten* *KL Auschwitz, Upper Silesia.*	

The elements of the Mauthausen Furnace are likewise listed in the Topf Bill of Lading of 12 January 1943 (Document 201, not translated) which we shall discuss later.

The design of the coke-fired double-muffle furnace is shown in Topf Drawing D57253, dated 10 June 1940, which refers to the first furnace set up in the Auschwitz Crematorium (Document 202). The description which follows is based on this drawing and on the examination of the Mauthausen Furnace, as well as on the documents concerning the double-muffle cremation furnace, Auschwitz Type, presented in this chapter. The numbers in parentheses refer to Documents 202a through e.

The furnace (photo 51) is enclosed in a solid outer brick structure by means of a number of anchoring bars (*Verankerungs-Eisen*) consisting of bars having a T-section (No. 1) a U-section (No. 1a) and an angled section (No. 1b; *T-, U- und Winkeleisen*), anchoring rods (*Anker*), bolts and nuts.

The dimensions of the Mauthausen Furnace are practically identical to those shown in Drawing D57253, which correspond to the dimensions of the anchor bars, as shown in the following table:

	Mauthausen Furnace	Drawing D57253	Anchor bars
Height	1,860 mm	1,850 mm	1,950 mm
Width	2,520 mm	2,500 mm	2,500 mm
Length (w/o gasifiers)	2,800 mm	2,780 mm	2,780 mm
Length (with gasifiers)	3,430 mm	3,380 mm	
Surface area (w/o gasifiers)	25 m²		
Surface area of gasifiers	7 m²		
Surface area, total	32 m²		

The furnace is equipped with two incineration chambers (*Einäscherungskammer*) or muffles (No. 2; Photos 52-56), each of which has the following dimensions:

Height:	700 mm
Width:	700 mm
Length:	2,000 mm
Surface area (w/o grate):	4.5 m²
Volume (including ash chamber):	1.4 m³

The lateral walls of the muffles possess four rectangular openings (Photos 52-54) linked to two air-supply channels (*Luftkanäle*; Photo 57) which run through

the sidewalls of the furnace parallel to the muffles and open up to the outside as two air-intake vents (*Lufteintritte*) closed by two raisable cast-iron doors (*Luftkanalverschlüsse*), 108 by 128 mm in size, at the front next to the corpse-introduction doors of the muffles (Photos 58f.). These channels allow feeding secondary combustion air to the muffles.

At the apex of the vaults of both muffles, in line with the longitudinal axis, we have the openings of four tubes (Photos 60f.) connected to the blower ducts (*Druckluftleitung*) coming from the blower itself (*Druckluftgebläse*). The function of this device is to feed combustion air to the muffle, especially if a coffin is used.

The central wall separating the two muffles has three rectangular openings (No. 3; Photos 62-65) some 210 mm × 270 mm in size. The thickness of the refractory brickwork is 260 mm. These openings are to ensure the heat exchange between the two muffles.

At the front (Photos 66), the muffles are closed by two cast-iron corpse-introduction doors (*Einführtüren* or *Einführungstüren*) 600 mm × 600 mm, opening to the outside. These doors are lined on the inside with refractory (Photo 67). In the center of the lower portion of the doors there is an air-feed hole closed on the outside of the door by means of a raisable cast-iron lid of standard type, which, however, has in its center a round inspection hatch (*Schauluke*), 45 mm in diameter (Photos 67f.). At the rear the muffles are closed by the refractory brickwork (Photo 65).

The floor of the muffle is constituted by a horizontal grate made of fireclay (*Schamotterost*; No. 5) consisting of five transverse fireclay bars (*Schamotteroststeine*; No. 6; Photos 52-54) on which the corpse was placed.

Underneath each grate, there is an inclined and V-shaped ash floor (*Aschenschräge*; No. 7) which ends in a narrower (340 mm) combustion chamber (No. 8; Photo 72) where the post-combustion (*Nachverbrennung*) of the corpse parts took place which had dropped through the grate. The front portion of the post-combustion chamber acted as an ash receptacle (*Aschenraum*; Photos 69-71). The ashes were extracted by means of dedicated scrapers (*Kratzer*) through the cast-iron ash-removal ports (*Ascheentnahmetüre*n; No. 9), 280 mm × 350 mm in size, positioned at the front of the furnace below the muffle doors (Photos 69-71). On the side walls of the two post-combustion chambers, towards the front of the furnace, are two rectangular outlets (No. 10) through which the discharge gases passed on into the two lateral flue-gas ducts (*Rauchkanäle*; No. 11) below ground. In the Mauthausen Furnace, the ash chambers of the two muffles are linked by a large opening in the central wall (Photo 72), whereas at Auschwitz the combustion chambers were separate.

The flue-gas ducts have a cross-section of 350 mm × 600 mm, and each one could be closed by a damper set into the duct (*Rauchkanalschieber*; No. 12), made of refractory material and measuring 350 mm × 600 mm as well, running vertically in a wrought-iron frame (*Rauchkanalschieberrahmen*) and operated by means of a cable (*Drahtseil*) and two rollers (*Seilrollen*). The rollers were welded to an anchoring bar which appears in Photos 100f.

Before reaching the chimney (*Schornstein*; No. 13a), the two flue ducts come together in a single duct which could be closed by means of the main damper of the flue duct (*Hauptkanalschieber*; No. 13) which operates like the secondary dampers.

On each of the side walls of the furnace we have an air-entry port (*Lufteintritt*) closed by means of a cast-iron cover of standard type, which can be raised (Photos 73f.); these openings are linked to two air channels each which open up inside the post-combustion chambers as two small rectangular openings on their external side walls (Photo 72) and were used to feed combustion air into these chambers. On the left side of the furnace one can see a portion of the compressed-air duct (*Druckluftleitung*; No. 14; Photos 75f.) which was originally connected to the blower (*Druckluftanlage*; No. 15) located below, at the point where the floor has no tiles.

The rear wall of the furnace sports a service pit (*Schacht*; No. 16; Photo 77) whose dimensions are 2,610 mm (width) × 1,540 mm (length) × 950 mm (height). It has four steps (No. 16a) and provides access to the two gasifiers, housed in a brick structure (No. 17; Photos 75, 77f.), measuring 2,520 mm (width) × 630 mm (length) × 1,430 mm (height). The corresponding dimensions of Drawing D57253 are 2,500 mm × 600 mm × 1,400 mm, respectively.

On the inclined top surface of this brick structure there are the two closures (*Generatorfülltüren*; No. 18; Photos 77f.) of the gasifiers' loading shafts (*Generatorschächte*; No. 18a; Photo 79) which open into the generators themselves.

The generators (*Generatoren*) are shaft-like chambers, closed below by the horizontal grates (*Planroste*; No. 20) of the hearths. The grates are constituted by eight square bars (*Vierkanteisen*) measuring 40 mm × 40 mm × 630 mm and four support bars (*Auflager-Eisen*) having the same section but a length of 740 mm (Photos 99-101). The grate itself measures 500 mm × 500 mm, or 0.250 square meters. The throughput capacity of the grate is about 30 kg/hr of coke.[460] In their upper portions, towards the muffle interior, the gasifiers narrow into the gasifier neck (*Generatorhals*; No. 21), which opens up into the muffle below the bars of the grate.

Up to the level of the fire bridge (*Feuerbrücke*; No. 22) in the neck, the gasifier has a volume of about 0.175 cubic meters.

Aside from the horizontal grate (*Planrost*; No. 20), the hearth (*Feuerung*) consists of the hearth door (*Feuertür*; No. 23; Photo 80) used for removing of coke slag and ash (hence it is also called ash-removal door – *Ascheentnahmetür*), and an air-feed opening (*Lufteintritt*) for the primary combustion air to the gasifier, equipped with a raisable standard cast-iron closure (Photo 81).

According to the "List of materials for a Topf double-muffle incineration furnace" dated 23 January 1943 (Document 203) the refractory mass of the furnace consisted of:

– 800 standard fireclay bricks, Type SS
– 800 standard fireclay bricks, Type A

[460] Quantity of coke burned on the grate in one hour. For the calculation of the throughput cf. Subchapter 8.3.

– 500 standard fireclay wedges, Type SS
– 400 standard fireclay wedges, Type A
– 1,400 kg of fireclay mortar
– 2,500 kg Monolite packing mass

The insulation of the furnace was assured by 1,300 white bricks of diatomaceous earth (insulating bricks) and 400 kg of insulating mortar. The standard bricks (*Normalstein*) measured 65 mm × 120 mm × 250 mm,[461] giving a volume of 1,950 cubic millimeters. The wedge or semi-wedge bricks (*Halbwölber*) measured 66/58 mm × 120 mm × 250 mm for a volume of 1,845 cubic centimeters.[462]

As the density of the fireclay bricks is about 1,800 kg/m³, the mass of the two types of bricks was:

$$\frac{1950\ \text{cm}^3 \times 1800\ \text{kg/m}^3}{10^6\ \text{cm}^3/\text{m}^3} = 3.51\ \text{kg and } \frac{1845\ \text{cm}^3 \times 1800\ \text{kg/m}^3}{10^6\ \text{cm}^3/\text{m}^3} = 3.32\ \text{kg, respectively.}$$ [108]

Hence, the mass of the furnace refractory brickwork was:

800 × 3.51 kg =	2,808 kg
800 × 3.51 kg =	2,808 kg
500 × 3.32 kg =	1,660 kg
400 × 3.32 kg =	1,328 kg
	8,604 kg

To this the mass of the fireclay mortar (1,400 kg) must be added, resulting in a total mass of about 10,000 kilograms. The Monolite caulking mass, being located in the space behind the insulation, is not counted as part of the refractory brickwork.

For the two gasifiers feeding the mobile oil-fired double-muffle furnace for the Gusen Crematorium, 1,000 normal and wedge-type bricks were used as well as 500 kg of fireclay mortar (Document 169), resulting in a total weight of roughly 4,000 kilograms.

Hence, the weight of the refractory brickwork of the double-muffle furnace can be split up in the following manner:

2 muffles of 3,000 kg each =	6,000 kg
2 gasifiers of 2,000 kg each =	4,000 kg
	10,000 kg

The post-combustion chamber is included in the weight of the muffle.

---

[461] *Brockhaus…* 1958, p. 632. These dimensions also appear in the letter from R. Koehler to *Zentralbauleitung* at Auschwitz dated 16 June 1942. RGVA, 502-2-23, p. 15.

[462] Letter from Topf to *SS-Bauleitung* of KL Gusen dated 24 February 1943. BA, NS4 Ma/54. In February of 1944 the sizes of the various types of refractory bricks were standardized and somewhat modified: the *Normalstein* measured 250 mm × 123 mm × 65 mm; for the *Halbwölber*, there were five types (2 H 6, -10, -16, -26, -38) with two fixed dimensions (height = 123 mm and longer side of base = 250 mm) and two variable ones (shorter sides of 68, 70, 73, 78, 84 and 62, 60, 57, 52 and 46 mm respectively). "*Erläuterungen zur Vereinheitlichung der Schamottesteinformate für den Feuerungsbau*," received by *Zentralbauleitung* on 17 February 1944. RGVA, 502-1-166, unpaginated flyer.

The Auschwitz Crematorium (Photo 86) was originally designed as shown on the Topf Drawing D57999 dated 30 November 1940 (Document 204). The second furnace had not yet been erected. The morgue (*Leichenhalle*) still had an L-shaped extension on the right-hand side.

Topf Drawing D59042 (25 September 1941) shows the positioning of the third furnace in the crematorium (Document 205). On this drawing, the extension of the morgue has been separated by a wall and has become a storage space for urns. The Central Construction Office Drawing 1241 of 10 April 1942 shows the definitive layout of the crematorium as of that date (Document 206). On 3 July 1942, this drawing was revised to show the location and structure of the new chimney (Document 207).

It is highly likely that the crematorium ceased its operation on 19 July 1943; the furnaces were torn down later. After the end of World War II, the Poles fabricated Furnaces 1 and 2, using the original parts which the SS had dismantled; many of these parts are still held in the former coal store of the crematorium (Photos 107-109), but some elements from the 8-muffle furnace were used as well.

In spite of the existence of the above drawing and probable advice from former detainees who had worked in the crematorium, the refabrication was carried out in a manner heedless of technical or historical accuracy. In the front portion, both the transverse anchor bars and the air channels next to the muffle doors are missing; moreover, the introduction doors of the two furnaces have been switched from one side to the other: the left-hand door to the right and vice-versa (Photos 87-91; cf. Photo 51).

In the rear portion, the brickwork of the gasifier is missing (Photos 97f.; cf. Photos 75, 77 and 78); the lids of the gasifier-loading shafts are set into a smooth vertical wall above the grates, as in an ordinary stove, and the hearth doors were placed underneath the former, like ash removal doors, again as in a normal stove. The furnaces could not have operated in this manner.

Due to this faulty refabrication, the two furnaces have been lengthened from about 2.80 to 3.40 meters. On the sides two closure devices for the air feed were mounted (Photo 96), the smaller one of which is original but in the wrong place (cf. Photos 73 and 74) whereas the larger one belonged to the 8-muffle furnace.

The rear part of the muffles was aged artificially, presumably by burning wood in the muffles (Photos 92-95).

The muffle grates consist of six shaped fireclay blocks (Photos 93-95) with slits of some 50 mm, which are neither in agreement with Topf Drawing D57253 nor with the grate bars of the Mauthausen furnace. The Topf bill of lading of 17 January 1941 (Document 197) mentions ten fireclay blocks for the grate (*Schamotte-Roststeine*) – five for each muffle – having a length of 56 mm and a total weight of 460 kg, thus 46 kg for each block. The digits indicating the length have been swapped by mistake, as can be seen from the Topf bill of lading dated 21 October 1941, which speaks of ten fireclay blocks for the grate, Type K6, having a length of 65 cm (total weight 440 kg) and ten more, Type K6a, having the same length (and weight). Each muffle, though, required only five such blocks, which would indicate that the other ten were surely spares.

In the furnaces of Crematorium I at Auschwitz there are currently six such blocks, which means that during the refabrication the furnace was made longer than it originally was. The blocks rested on the brickwork of the post-combustion chamber, about 25 mm from the muffle walls, which means that the muffles were 700 mm wide; the joints were filled with refractory mortar. This type of grate was not intended for a rapid cremation, because with slits of hardly 50 mm, combustion takes place entirely in the muffle, with only the ash itself dropping down into the post-combustion chamber; the initial part of a cremation taking place in the main combustion chamber is thereby prolonged considerably as compared to the time required with grates with wider openings.

In the foundations of the third furnace, which was not rebuilt, the remains of the hearth grates can still be seen (Photos 100f.). The grates consist of seven longitudinal square bars (Photo 99) supported by two square bars placed transversely (Photo 101); the cross-section (40 mm × 40 mm) and the length of the longitudinal bars (630 mm), as well as that of the supporting bars (740 mm) are the same as indicated in Topf's bills of lading of 17 January and 21 October 1941. The first document mentions 34 supporting bars, but this is a mistake, as we can see from the second document as well as from the bill of lading dated 12 January 1943 and the one dated 24 February 1943 (Document 208, not translated) which have 30 square bars 40 mm/40 mm × 630 mm and four bars 40 mm/40 mm by 740 mm for the gasifier grates. Fifteen grate bars and two supporting bars were thus shipped for each gasifier.

The original grates that are still visible and the respective width of the gasifier necks (some 50 cm) exclude the possibility that the fifteen bars for each one of the hearths were mounted all at the same time. The left-hand grate of the third furnace has seven bars, but one has been removed; we may hence rightly assume that the grates initially consisted of 8 bars.

The discharge-gas system is shown in Topf Drawing D57253 for the first furnace (Document 202; in particular Documents 202a, 202b, and 202d), and D59042 for the third (Document 205). At the Auschwitz Crematorium, the outlets of two smoke ducts are still visible in the foundations of the third furnace (Photo 102).

Each furnace had its dedicated blower device (*Druckluftanlage*; for the first furnace cf. Document 202b, No. 15) consisting of the blower itself (*Druckluftgebläse*; No. 15a), driven by a directly mounted 3-phase electric motor of 1.5 hp (No. 15b), and the air conduits (*Druckluftleitung* or *Rohrleitung*; No. 14). Structure and operation of the blowers will be discussed in the next chapter.

For the first and the third furnace, the blower is shown in Drawings D57253 and D59042, respectively, and for the second furnace it is mentioned in the quotation of 13 November 1940 (Document 193).

Originally, the chimney (*Schornstein*; Document 202e, No. 13a) had a square cross-section, 500 mm × 500 mm. The draft enhancer (*Saugzug-Anlage*; Document 202e, No. 13b), which had a capacity of about 4,000 m³/hr of spent gas, consisted of a blower (*Saugzug-Gebläse*; No. 13d) driven by a directly mounted 3-phase 3-hp electric motor (No. 13c) and a rotary vane (*Drehklappe*)

separating the intake chamber from the compression chamber. The operation of this device is explained in Topf's service instructions (Document 209):[463]

> *"Operating instructions for the Topf draft enhancer.*
> *If the draft of the furnace is insufficient, the draft enhancer mounted on the chimney must be started up.*
> *Care must be taken to start the motor first, and only then the damper in the chimney may be closed. The water supply for the water-cooled bearing must run at all times.*
> *After the end of the incineration, the rotary vane in the chimney must be opened first, before the motor and the cooling water are stopped.*
> *Furthermore, it is necessary to make sure that there is always enough water in the tank."*

Topf's cost estimate of 13 November 1940 does not speak of a draft enhancer. The explanation is provided by Topf's letter of transmittal in which we can read:[464]

> *"As we assume that this furnace will be connected to the same chimney of the present crematorium, the purchase of a further draft enhancer is not necessary as* [the existing one] *can be used in alternation for both furnaces. It is also possible to operate both furnaces* [simultaneously] *with this device."*

The draft enhancer is not mentioned either in Topf's bill of lading of 21 October 1941, nor in the final invoice for the third furnace because this furnace was connected to the existing device as well; this is confirmed by Drawing D59042 showing only one draft enhancer in the space between the buidling and the chimney.

As we have seen in Chapter 6, the chimney of the crematorium was taken down and replaced by another between June and August of 1942. The new chimney, displaced some 10 meters along the axis of the old one, had a square cross-section 0.90 m × 0.90 m and was 15 m high (Document 178). The three double-muffle furnaces of the crematorium were linked to it by means of two flue ducts, 0.70 m × 0.80 m, which had a refractory lining 12 cm thick. The duct in line with the old chimney, having a length of 12.20 m, was used for Furnaces 1 and 2, the transverse one, 7.375 m long, for the third furnace (Document 179).

The loading system of the muffles themselves consisted of a corpse-introduction device (*Leicheneinführungs-Vorrichtung*) having a coffin-loading cart (*Sargeinführungswagen*) moving on rails (*Laufschienen*; Document 202b, No. 24) and a semi-cylindrical cart (*Verschiebewagen*) running above it. These devices are still visible today in the Auschwitz Crematorium (Photo 87). Their operation can be described in the following manner:

In front of each one of the three furnaces are two rails set into the floor for moving the cart; perpendicular to these rails are connected two wider rails which carry a rotatable platform (*Drehscheibe*) mounted on a flat cart (Document 205a, No. 25 and 26, and Photos 105f.). This platform enabled the carts to be moved from one set of rails to the other.

[464] RGVA, 502-1-327, p. 166.

In the ceiling of the furnace hall of the Auschwitz Crematorium, above the first and the second furnaces, we have two ventilation shafts (Photo 103) opening up into two small shafts (Photo 104) on the flat roof of the crematorium.

The crematorium chimney shown in Photo 86 was rebuilt by the Poles after the war. The administration of the Auschwitz Museum has attached a commemorative plaque to the wall next to the second furnace, bearing an inscription in four languages (Polish, English, French and Russian), stating (see Photo 110):[465]

> *"Crematorium I was working in the period from 1940 to July 1943. About 70000 corpses prisoners, gased, shot, killed at work or deceased in camp, were cremated here."* (Bad English in the original)

The operation of the double-muffle furnace is explained in Topf's operating instructions (Document 210). For the sake of clarity, I have added comments and references to the photos and other documents concerning the furnace in brackets […]. Text in normal parentheses (…) appear in the original text.[466]

> *"Operating instructions for the coke-fired Topf double-muffle incineration furnace.*
>
> *Before any coke is fed to the two coke generators* [Photo 78, through the two loading shafts, Photo 79]*, both flue-duct dampers* [Documents 202b & 202d] *on the furnace must be opened, as well as the main flue-duct damper* [Document 202e, No. 13] *and/or the rotating vane* [of the Saugzuganlage] *on the chimney.*
>
> *Now fire can be lit and maintained in the two generators; care must be taken to make sure that the secondary covers to the right and left of the ash-removal doors* [Photos 78 and 81] *(coke generator) are open.*
>
> *Once the incineration chamber shows a satisfactory red glow (about 800°C), the corpses can be introduced successively into the two chambers.*
>
> *At this point, it is advisable to switch on the air compressor located at the side of the furnace* [Document 202b, No. 15] *and to let it run for about 20 minutes. By observation, it must be decided whether too much or too little fresh air enters the two chambers.*

>
> *As soon as the corpse parts have dropped from the fireclay grate* [Photo 52] *onto the inclined ash-plate below* [into the post-combustion chamber, Photo 72]*, they must be moved forward towards the ash-removal door* [Photo 71] *by means of the scraper. These parts may remain here for another 20 minutes for post-combustion. Then the ash is transferred into the ash container and set aside for cooling.*
>
> *In the meantime, new corpses will be introduced successively in the chambers.*
>
> *The two generators must be loaded with fuel from time to time. Each night the generator grate must be freed of coke slag and the ash must be removed.*
>
> *It is important, furthermore, that after the end of the operation as soon as the generator has burned itself out and embers are no longer present, all air damp-*

[465] The brickwork of the furnaces could last for some 16,000 cremations. See Subchapter 9.7. in this Unit.

[466] APMO, BW 11/1, p. 3.

ers and doors [of the ash chambers, the gasifiers' loading shafts, of the muffles' ash chambers, and of the introduction doors]*, as well as the flue-duct dampers, must be closed in order to avoid cooling of the furnace.*
After each incineration, the furnace temperature will increase. Therefore, care must be taken not to let the internal temperature exceed 1100°C (white hot).
This temperature increase can be avoided by feeding air.
26 September 1941" (Emphasis in original)

7.2. The Coke-Fired Triple-Muffle Furnace

The Topf Co. built a total of 14 triple-muffle furnaces: ten for the Birkenau Crematoria II and III, two for the Buchenwald Crematorium and two for the crematorium at the Gross-Rosen Camp. Practically nothing is known about the furnaces for the last camp. In 1948, the Soviet counter-espionage service (SMERSH) was in possession of the documentation of a project, elaborated by Topf in 1941, for the crematorium of Gross-Rosen, which did, in fact, concern two triple-muffle furnaces. Their installation was confirmed by engineer Prüfer.[467] In his interrogation of 21 March 1946, he declared to have designed the triple-muffle furnace himself, together with Ludwig Topf, as early as 1939. The respective projects had then been submitted to the War Ministry and were accepted by the SS in 1940.[468]

This statement is, however, in disagreement with a letter dated 6 December 1941, addressed by Prüfer to the two co-directors of the firm, Ludwig and Ernst Wolfgang Topf, in which he stated that he had designed the triple- and eight-muffle furnaces by himself, essentially in his spare time.[469] However, no documentary trace dated earlier than the end of 1941 exists for these two furnace types; hence, they were most-likely designed at that time (1941).

On 22 October 1941, the New Construction Office at Auschwitz ordered from Topf "5 Topf triple-muffle furnaces with blower," as well as "2 Topf draft enhancers for about 10,000 m³ of exhaust gas each" and "1 waste incinerator"[470] for the new crematorium which at that time the Auschwitz camp authorities were still planning for the Auschwitz Main Camp.

In the "Explanatory report for the preliminary project for the new construction of the *Waffen-SS* PoW camp at Auschwitz, Upper Silesia," dated 30 October 1941, one reads:[471]

"On account of the considerable quartering (125,000 prisoners) a crematorium will be built. It contains 5 furnaces with 3 muffles each for two men, and will thus allow incinerating 60 men in one hour. Furthermore, a corpse cellar as

[471] *Erläuterungsbericht zum Vorentwurf für den Neubau des Konzentrationslagers der Waffen-SS*, Auschwitz O/S. RGVA, 502-1-233, p. 20; cf. Document 211.

> *well as a waste incinerator will be installed. The crematorium will be erected within the area of the* K.L.*"*

The furnaces mentioned in this report were of a design different from the ones which were later built. They were, in fact, conceived to accommodate two corpses in each muffle and would thus have required larger muffles and generators. We can gather this also from page 6 of the explanatory report where the estimated cost for the five triple-muffle furnaces is listed as being 60,000 RM (Document 212), whereas the Topf estimate for the five triple-muffle furnaces actually built in Crematorium II at Birkenau not only has a much-lower price (51,237 RM, including the two coffin-loading devices and the three draft enhancers), but also shows a later date (4 November 1941). In addition, the operating instructions supplied by Topf to the Auschwitz Central Construction Office specify that the corpses be loaded "*hintereinander*" (Document 227), *i.e.* successively. This means that the furnace was not designed for the simultaneous incineration of two corpses in one muffle.

According to Pressac, the first two triple-muffle furnaces built by Topf were started up in the crematorium at the Buchenwald Camp on 23 August and 3 October 1942, respectively (Pressac 1993, pp. 116f.; 1994, pp. 130f.).

The parts for the five triple-muffle furnaces at Crematorium II are listed in the Topf bills of lading of 16 April[472] and 18 June 1942.[473] The shipment of 16 April included also several parts of the double-muffle furnace at Mauthausen – shipped to Auschwitz by mistake and with an erroneous reference to the order for the third furnace at the crematorium of the Main Camp (*Auftrag 41/1980/1*) – and with the blower for this crematorium (*Auftrag 41 D 314*). The shipment of 18 June included some parts for the waste incinerator (*Müllverbrennungsofen*) of Crematorium II.

The main elements of the five triple-muffle furnaces listed in the two above documents are the following:

<u>Parts for the Topf triple-muffle furnace</u>

- 15 *Einführungstüren* (introduction doors) 600 × 600 mm, 10 right-handed and 5 left-handed
- 30 *Feuertüren* (closures for the hearths and the ash chambers) 280 × 350 mm and 2 of 250 × 250 mm
- 56 *Luftkanalverschlüsse* (closures for air channels) 108 × 128 mm
- 10 *Füllschachtverschlüsse* (closures for loading shafts for the gasifiers) 270 × 340 mm
- 6 *Rauchkanalschieber* (flue-duct dampers) 600 × 700 mm
- 5 *Gebläse* (blowers) No. 275,[474] 2 clockwise and 3 counter-clockwise

[472] RGVA, 502-1-313, pp. 167-170. Topf, *Versandanzeige*, 16 April 1942; Document 213.
[473] RGVA, 502-1-313, pp. 165f. Topf, *Versandanzeige*, 18 June 1942; Document 214.
[474] The number of the blower corresponded to the diameter (in mm) of the tube on the pressure side.

Parts for the flue ducts and the chimney

– 5 *Fuchseinsteigeschachtverschlüsse* (access ports for the flue ducts) 450 × 510 mm
– 1 *Reinigungstür* (cleaning door for chimney) 390 × 510 mm
– 3 *Rauchkanalschieber* (flue-duct dampers) 1200 × 800 mm
– 3 *Schieberplatten* (damper plates) 1250 × 840 mm
– 3 *Gebläse* (blowers) No. 625.

The bill of lading of 16 April 1942 mentions, moreover, a "*zweiflügelige Feuertür*" (double door for hearth) 600 mm × 600 mm which surely belonged to the waste incinerator.

The two above lists contain more shipment errors: the air-channel closures for the five furnaces numbered not 56 but 55, or eleven for each furnace, placed at the following points: one placed on each introduction door of the muffles (*i.e.* 3 per furnace), two placed next to the introduction door of the right-hand muffles and two for the left-hand muffles, as well as two behind the center muffles (*i.e.* six per furnace), and one on the closure of each gasifier hearth (*i.e.* two in total). Furthermore, the two *Feuertüren* 250 mm × 250 mm did not belong to the triple-muffle furnaces and, finally, neither one of the advices has the grate bars for the hearths or the grate bars for the muffles.

Topf's overall supply for the five triple-muffle furnaces at Crematorium II is detailed on the final invoice dated 27 January 1943 (Document 215) translated below:[475]

Object *BW 30 = Crematorium II*	*Amount* *RM*
41 D 2249	
Construction of 5 pcs. triple-muffle incineration furnaces, viz.: *Supply of normal, wedge-type, and special fireclay bricks, fireclay mortar and Monolite packing mass for the construction of the fire-resistant brick structure of the furnace, of cast- and wrought-iron fittings for furnace and compressed-air units as per description in our cost estimate of 4 November 1941, item I.* *Supply of an erection supervisor for furnace construction, including daily rates, travelling expenses and social-security contributions.* *Transportation of building materials to Erfurt Station @ 6,378.--* *Supply of 2 coffin-introduction devices each consisting of a coffin-introduction cart, shoving cart, and rail system for 5 incineration furnaces*	*31,890.--* *1,780.--*
Subtotal	*33,670.--*
Supply of: *10,000 normal refractory bricks, Seger Cone 30* *3,000 wedge-type refractory bricks, Seger Cone 30* *7,000 kg of mortar M 2* *and*	

[475] Topf, *Schluss-Rechnung Nr. 69* dated 27 January 1943. RGVA, 502-2-26, pp. 230-230a.

Supply of our technician for construction of smoke installation	*4,045.--*
Supply of 3 Topf draft enhancers in suction, each consisting of 1 blower in suction for an output of 40,000 m³ of smoke gases against a total pressure of 30 mm water column with 2 suction fittings, mounted, and 1 pressure fitting, 1 smoke-channel-blocking damper 0.9 by 1.2 m, with air-tight guide, rollers cable and hand crank, 1 380-Volt 50 c/s 3-phase motor, spray protected, nominal output 15 hp with slip-ring rotor, full-load starter and buffered-bolt clutch,	
Supply of our technician for installation @ 3,016.-- each	*9,048.--*
Construction of a waste incinerator, viz:	
Supply of normal, wedge-type, and shaped fireclay bricks, fireclay mortar, Monolite packing mass, bricks of diatomaceous earth, insulating mortar and rock wool for erection and insulation of fire-resistant furnace brickwork, cast- and wrought-iron fittings, wrought-iron loading box, and smoke-channel damper,	
Supply of our erection supervisor for construction work. Delegation of an engineer for start-up, as per our cost estimate of 4 November 1941 and our letter of 4 November 1941.	*4,474.--*
	51,237.--

KL Auschwitz KGL – second crematorium.		

The description of the Topf triple-muffle furnace which follows is based on the documents presented in this subchapter, and on a direct investigation of the two Buchenwald Furnaces; it is supported by four drawings (Documents 217-220) and by the photos in Section V of the collection of photos. The numbers in parentheses refer to the above drawings.

Three photos taken by the SS confirm that the triple-muffle furnaces set up in Crematoria II and III at Birkenau were of the same type as those in the crematorium of the Buchenwald Camp, though one of the latter was designed to also use oil as fuel (Photos 111-116).

As far as its layout is concerned, the triple-muffle furnace consisted basically of a double-muffle furnace with a third muffle inserted in the middle, as well as some other technical modifications to be described below.

The furnace itself is held in a solid brick structure by wrought-iron T, U, and angular anchor bars, tightening rods, bolts and nuts. Its dimensions are as follows:

Height	2,000 mm
Width	3,460 mm
Length (w/o gasifiers)	2,780 mm
Length (with gasifiers)	3,400 mm
Surface area of the furnace without gasifiers	33 m²
Surface area of the gasifiers	10 m²
Overall surface area	43 m²

The furnace is equipped with three cremation chambers or muffles (No. 1) each of which has the following dimensions:

Height	800 mm
Width	700 mm
Length	2,000 mm
Surface area (w/o grate)	5 m²
Volume (including ash chamber)	1.5 m³

At the apex of the vault, arranged along the longitudinal axis, each muffle has four rectangular openings 100 mm × 80 mm in size (No. 2; Photos 132f., 137, 139, 143, 146), which lead into a horizontal duct running lengthwise inside the muffle ceiling (No. 3). These three ducts merge into a transverse and common duct located behind the furnace, which exhausts to the outside and is connected with a pipe (No. 25) to the blower (No. 23f.), which feeds combustion air into all three muffles jointly, especially in cases of incineration with a coffin.

The side walls of the outer muffles had four rectangular openings (Photos 131, 140f., 147), 110 mm × 130 mm, linked to the two air channels which ran lengthwise through the two outer walls and ended in two air inlets at the front (Photos 149, 151) closed by two raisable cast-iron covers (Photos 148, 150, 153) of standard size (108 mm × 128 mm) and shape. The two air channels at the rear of the furnace turned downwards 180° and ran back; the four inlets mentioned were arranged in this section of the channel as we may deduce from the fact that the respective covers are located higher than the openings set into the muffle. These channels served to bring combustion air to the outer muffles.

The center muffle was connected to the outer ones by three large openings of some 200 mm × 300 mm set into each of its side walls (No. 4; Photos 135-138). These outlets passed through the refractory brickwork (about 250 mm thick) on both sides and discharged through the inner walls of the outer muffles (Photos 134, 140, 142, 144f.). These openings are part of the discharge system of the combusted gases; for that reason, as opposed to the design of the double-muffle furnace, they are essential for the operation of the furnace.

The two walls separating the inner muffle from the outer ones had a thickness which was too thin to place any combustion-air channel in them similar to the design of the outer muffles; instead, the air channel to the center muffle was set into the brickwork of the rear portion of the furnace, opening on the inside into the muffle through a rectangular opening located near the top in the center of the muffle‘s rear brick wall (Photos 135-137), and at the outside into an opening (Photo 170) located in the rear wall of the furnace between the two gasifiers; it could be closed by means of a standard-sized raisable cast-iron cover (Photo 168). This exterior opening is located lower than the opening inside the muffle itself. The channel therefore is not a straight horizontal duct; coming from the inside, it angles down 90°, then angles 90° back to exit as a horizontal duct.

The muffles are closed at the front by three cast-iron corpse-loading doors, 600 mm × 600 mm (No. 5; Photo 127) clad with refractory on the inside (Photo 129). In the lower central part of the doors is an air inlet, closed on the outside by means of a standard-sized raisable cast-iron cover, which has at its center an inspection hole 45 mm in diameter covered by a round cast-iron plate held by a hinge. The upper part of the door sports another inspection hole, also closed by a thin metal plate rotating around a pin (Photos 127, 129).

At the rear, the muffles are closed by refractory brickwork. Their lower part consists of a horizontal grate (No. 6) composed of five refractory bars (No. 7; Photos 122, 136, 145, 147) some 90 mm thick in their upper part, spaced some 210 mm apart, on which the corpse would be placed.

Below each grate was located the inclined V-shaped ash plate (No. 8; Photos 131, 140f.), which ended in a narrower post-combustion chamber (No. 9; Photos 156f.), in which the corpse parts that had dropped down between the bars burned out completely, hence the name post-combustion chamber. The front part of this chamber constituted the ash chamber as such. The glowing ash was extracted by means of dedicated scrapers through the ash-removal openings (No. 10) located at the front of the furnace below the loading doors of the muffles. They then fell into the ash receptacles placed in front of the furnace on the floor of the furnace hall (Photo 155).

On the sidewalls of the post-combustion chamber of the center muffle, in its front portion, were two large rectangular discharge openings (No. 11; Photo 156) through which the combusted gases flowed into two short vertical channels (No. 12) which, in turn, led to the flue duct (No. 13) located beneath the furnace, as shown in Documents 219f. The flue duct connecting the furnace to the chimney could be closed by an appropriate fireclay vane running vertically in a frame. It was operated by means of a metal cable, a pulley, a manual crank, and a counterweight. A cement counterweight with a hole can be seen in Photo 172; Photo 168 shows the manual crank.

At the center of the rear wall of the post-combustion chamber, below the air-channel opening feeding air into the upper part of the muffle, is the opening of the straight secondary air channel into the center muffle's post-combustion chamber (Photo 171), which can be closed by a raisable standard-type cast-iron cover (see Photo 169).

The post-combustion chambers of the outer muffles have solid side walls (Photo 157). Combustion air was fed into them through a channel ending on the outside at the front of the furnace located below the air-channel opening feeding air into the muffle itself (Photos 148, 150, 152f.). It, too, had the usual raisable standard cast-iron cover. This channel makes a 90° downward turn and then bends once again into the horizontal, running parallel to the post-combustion chamber to which it is connected by appropriate openings (in Photo 157, these openings are covered by trash which has fallen into the post-combustion chamber).

Behind the rear part of the furnace, there is a service pit with four steps (No. 14), some 880 mm deep (Photo 158). It allows access to the two gasifiers, each with its own brick housing, set behind the outer muffles (No. 15; Photos 158f., 205); the housing is some 1,380 mm wide and 1,280 mm high up to the upper edge of the inclined plate.

On the inclined plate, some 900 mm long, there is the cover of the gasifier's loading shaft measuring 270 mm × 340 mm (No. 16; Photos 160-162). This shaft opens into the upper part of the gasifier (No. 17; Photos 163f.).

As the loading ports of the gasifiers are relatively high above the floor of the service pit, a metal step has been placed in front of the gasifiers at the floor level of the furnace hall (Photos 199f.).

The gasifier (No. 18) is a shaft-like chamber, closed below by the horizontal grate of the hearth (Photos 167, 174, 177) consisting of twelve square bars 40 mm × 40 mm × 630 mm, held by two standard bars of the same cross-section

but having a length of 740 mm. The grate measures about 600 mm × 500 mm, or 0.3 square meters. The throughput capacity of the grate is about 35 kg of coke per hour.

At the top, towards the inside of the furnace, the gasifier narrows into a neck which opens up in the rear part of the post-combustion chamber (No. 19; Photos 140-142).

The generator consists of the hearth which includes, besides the horizontal grate, the hearth's ash-chamber door (No. 20; Photos 165, 173, 175f.), which is used for the removal of the ash from the ash compartment and for cleaning the grate, *i.e.* for the removal of the coke slag, as well as the channel for the combustion air to the gasifier, which has its inlet (Photo 166) on the outside next to the hearth door, but somewhat higher up; it can be closed by means of the usual standard cover (Photos 165, 173, 175f.).

The Buchenwald Furnace, designed for use with oil, has two burners set into the rear part of the brickwork, above the gasifiers and behind the outer muffles (Photos 200f.) entering inside by means of a round opening in the muffles' rear wall (Photos 130, 139). Above the furnace we have the cylindrical oil tank (Photos 114-121, 200-203) with a diameter of about 400 mm and a length of about 2.5 m. It is accessible by means of an iron ladder welded onto the lateral anchoring bars of the furnace (Photo 203). The tank fed each burner through a flexible tube connected to a metal pipe, which itself was connected to the upper part of the burner (Photos 201f., 204); its lower part was connected to the compressed-air tube having a larger cross-section (Photo 204).

Two blowers are located between the two furnaces (Photo 188). The front blower (Photos 189-191) fed air into two large pipes, each of which was connected to the air-feed channels set into both furnaces' walls (Photos 188, 192f.). Each pipe was equipped with a butterfly valve for the control of the air-flow rate (Photos 192, 194).

The rear blower (Photos 195-197) was connected to a pipe located above the gasifiers, which fed air into the burners of the furnace that could also be fueled with oil (Photos 197-201).

The corpse-introduction device (*Leicheneinführungs-Vorrichtung*) consisted of a cart for the introduction of the coffin (Photos 181-183), running on rails (*Laufschienen*; Photo 184), and of a semi-cylindrical cart running above it (*Verschiebewagen*; Photos 182f.). At its front end, the coffin-introduction cart was equipped with a metal stretcher some 2,700 mm long, on which the corpse was placed and which was introduced into the muffle (Photo 185).

The stretcher consisted of a wrought-iron plate with two side plates welded to it, forming a ⊢⊣ shape. The top parts of that plate (Photo 185) kept the corpse from falling off during the positioning of the cart, while the lower ones ran on a pair of wheels (*Laufrollen* or *Einführrollen*; Photos 186f.) attached to a movable frame (Photos 178f.) which was itself threaded through a mounting bar (*Befestigungs-Eisen*) welded to the anchoring bars of the furnace below the muffle doors (Photos 117, 122). Pushing the introduction cart towards the open muffle, the two lower side plates inserted themselves into the concave rims of the wheels (Photos 186f.), and ran along them, thus allowing the corpse to be

moved easily into the muffle (Photo 185). Next, the semi-cylindrical cart was pushed forward over the stretcher (Photos 87, 89) into the muffle, until its front part touched the corpse; finally, the introduction cart was withdrawn, whereas the semi-cylindrical cart was held firmly in place within the muffle, pressing downward with the stoker attached to its rear part in such a way that the introduction cart below could move out of the muffle while the corpse slipped onto the grate. The movable frame with the wheels could slide laterally on the mounting bar and was thus used for all three muffles of one furnace.

In front of each muffle, on the floor of the furnace hall, there is a pair of rails for the corpse-introduction carts. These rails are connected to another pair of rails running the whole length of the furnace room (Photos 181, 184), up to the corpse elevator. The layout of the rails is similar to the arrangement used in the old Auschwitz Crematorium (Photo 105).

The style of the Buchenwald crematorium (Photos 207f.) is very similar to that of Crematoria II and III at Auschwitz. The crematorium has an underground morgue, accessible via a stairwell to the left of the chimney (Photo 208). The corpses were taken there by way of a slide (Photo 210), the upper end of which was closed by means of a trap-door (Photo 209). Opposite its lower end was a steel elevator (Photos 212-215), which went up to the furnace hall above (Photos 214f.). Photo 206, taken after the capture of Buchenwald in April 1945, shows a U.S. soldier standing in front of the furnace equipped for oil firing.

The design of the triple-muffle furnaces at Birkenau was essentially the same as that of the Buchenwald furnaces described above, with only very slight differences (Photos 111, 113, 115):

– The muffle doors did not have the upper inspection port (Photos 115 and 128).
– The closures of the air channels for the combustion air to the muffle and to the outer post-combustion chambers were placed lower; from their position (Photo 115) one may deduce that the combustion-air channels were straight, *i.e.* they ran in the furnace wall parallel to the muffles and to the ash chambers without any bends.
– Each furnace had its own blower, No. 275. These blowers, two counter-clockwise blowers and three clockwise blowers, were positioned as shown in Document 222a.

The way the doors opened was the same as for the Buchenwald furnaces: the door of the left-most muffle opened to the left, the other two to the right.

No document I know precisely indicates the mass of the refractory masonry of the triple-muffle furnace. The figure I had assumed hypothetically in the first Italian and English editions of the present work (2012/2015, Vol. I, pp. 323/273f.), as listed in the invoice of January 27, 1943 (DOCUMENT 215), seems to refer to the smoke ducts rather than the furnaces. It is known, however, that the triple-muffle furnace was practically nothing other than a double-muffle furnace with a third muffle inserted in the middle (without its gasifier); since the refractory masonry of half the furnace weighed 5,000 kg (3,000 kg for the muffle including the ash chamber and 2,000 kg for the gasifier), the maximum mass of

the triple-muffle furnace was 5,000 (lateral muffle + gasifier) + 3,000 (center muffle) + 5,000 (lateral muffle + gasifier) = 13,000 kg. The actual mass was undoubtedly lower, because Topf's policy was to save as much material as possible, as shown by the eight-muffle furnace, whose refractory masonry weighed 24,100 kg (see further below). Assuming a standard mass for the four gasifiers of 2,000 kg each, hence a total of 8,000 kg, for the eight muffles there would remain ([24,100 – 8,000] ÷ 8 =) about 2,000 kg per muffle. It is therefore probable that for each muffle of the triple-muffle furnace, the Topf Company had foreseen a more-or-less-intermediate mass, around 2,500 kg, and that the total mass was around 11,500 kg.

In comparison with other furnace types, the triple-muffle furnace was a simplified device, as one can also see from its low price. The third double-muffle furnace for the old Auschwitz Crematorium cost 7,332 RM, including the blower and a corpse-introduction system with the necessary rails, whereas the furnaces for Crematorium II ran to 6,378 RM each, including the blower. As the two introduction carts and the rails for five furnaces were billed at 1,780 RM, the triple-muffle furnace was actually cheaper than the double-muffle type, including the same accessories for both. The unit price of the furnaces at Crematorium III, however, was slightly higher at 7,830 RM (without the corpse-introduction cart), but it was still very economical.

The drawings shown in Documents 221 and 222 refer to Crematorium II, but apply also to Crematorium III, the mirror image of Crematorium II. The Birkenau Crematoria II and III each had a capacious furnace hall (Document 222a, No. 1) measuring 30 m × 11.24 m. The five triple-muffle furnaces were arranged lengthwise, as shown in Photos 111, 113 & 115. In front of each muffle there were three pairs of rails (No. 2) connected to two rails for loading the furnaces (No. 3) running perpendicularly to the former towards the elevator (No. 4). These rails supported a rotatable disk, mounted on metal rollers, which one can just about make out in Photo 115; the set-up in the old crematorium at the Auschwitz Main Camp had been similar (Photo 106).

The ruins of the furnace hall at Crematorium II (Photo 216) still show the rails located in front of the muffles (Photos 217f.); the traverse rails connecting them, on the other hand, have been removed, but the grooves into which they were set were not filled with cement (Photos 219f.), which means that the rails were probably taken out some time after the crematorium had ceased operating but before it was blown up.

Behind the furnaces was another pair of rails for the coke supply of the gasifiers (No. 5); they ran parallel to the side walls of the furnace hall and right in front of the five gasifiers' service pits, and went as far as the coke-storage area (No. 6).

A side wing of the crematorium, some 10 m ×12 m, was located next to the furnace hall. It was divided into two rooms by a partition. The smaller room, which could be reached from the furnace hall, was itself split into three rooms: two for the motors (Nos. 7, 9) and one room for one of the three draft enhancers (No. 9) which were originally built for this crematorium. The other room contained the chimney (No. 10) as well as the other two draft enhancers (Nos. 11f.)

and the waste incinerator (No. 13), from which this room took its name (*Müll-verbrennungsraum*; No. 14).

The waste-gas-discharge system was designed as follows: The gas produced in the gasifiers entered the outer muffles through the gasifier neck, passed on into the center muffle through the six holes between the muffles, flowed into that muffle's post-combustion chamber, left through the two openings in the side walls and then flowed on into a flue duct, which had a cross-section of 60 cm × 70 cm and was located beneath the furnace (Documents 219f.; No. 13). Each flue duct had its own damper (*Rauchkanalschieber*), 60 cm × 70 cm, located at the furnace's rear end, as on the H. Kori furnaces at Dachau (Photos 258f.), and running vertically along the rear wall of the center muffle (Document 220; No. 14).

The crematorium had a total of six flue ducts (Documents 223, 223a), one for each of the five furnaces and one for the waste incinerator. Each pair of ducts merged into a single duct, which led to one of the three smoke ducts into which the chimney was divided. The ducts of Furnaces 1 and 2 went into the smoke duct on the left, those of Furnaces 3 and 4 into the central smoke duct, and those of Furnace 5 and the waste incinerator into the smoke duct on the right. At the flue ducts' merging point, their cross-sectional dimensions increased from 60 cm × 70 cm to 80 cm × 120 cm (the cross-section of each of the chimney's smoke ducts) in order to compensate for the potentially doubled volumetric flow.

Each of these three smoke ducts was connected to a draft enhancer through a short vertical shunt as shown in Document 224a (No. 26 & 28); at the end of the three vertical shunts, below the corresponding blower, was a moveable damper plate (*Schieberplatte*; No. 27), 125 cm × 84 cm in size, which, by closing of the vertical duct, allowed the chimney to function under natural draft.

The draft enhancer's blower was of a type as shown in Photo 195, but much larger. It sucked in a part of the combustion gases through an appropriate opening (No. 29) and released them at a high flow rate into one of the chimney's smoke ducts (No. 31), thus creating a strong drop in the gas pressure, which then caused more gas to flow from the flue ducts into the smoke duct. The three blowers each had a capacity of 40,000 m³ of combustion gas at a pressure of 30 mm of water column. Just before the chimney were located three dampers (*Rauchkanalschieber*), 80 × 120 cm in size, running vertically and allowing the chimney's smoke ducts to be closed against the flue ducts feeding into them (No. 30).

The chimney, which had a height of 15.46 m, was divided into three smoke ducts with a cross-section of 80 cm × 120 cm (Nos. 31f.) each. Its foundations are still visible in the rubble of Crematorium II (Photo 221).

The waste incinerator, in all likelihood, was the *Müll-Verbrennungsofen MV* (Document 225, 225a) described in Topf's leaflet quoted in Chapter 3 (Document 161). The waste incinerator for Crematorium III was ordered by telephone on 5 February 1943, and confirmed in writing on 11 February. It cost 5,791 RM all-inclusive (Document 226).

As we have already mentioned, the draft enhancers of Crematorium II were seriously damaged in March of 1943 and had to be dismantled. In view of this, the respective devices for Crematorium III were never installed. Nor was Crematorium III equipped with loading rails for the introduction of corpses as discussed above; the introduction carts were replaced by standard stretchers (Document 216). These stretchers, also used for the Topf Furnaces at Mauthausen, consisted of two parallel metal tubes, 3 cm in diameter (Photos 83-85) and 350 cm long. A slightly concave metal plate, 190 cm long and 38 cm wide (Photos 52f.), was welded to the front part of these tubes, *i.e.* to the portion which was inserted into the furnace. To ensure a better way of handling them, these tubes, over the rest of their length were set further apart (49 cm) by means of two elbow bends (Photos 67 and 84). The distance between the tubes at the leading end corresponded to the spacing of the guide rollers (*Führungsrollen*) at the lower end of the furnace doors; they could thus be placed on them with ease (Photos 84f.).

Towards the outside, the two tubes which supported the metal plate had two stops consisting of two steel bars which were welded to the underside of each tube in the shape of a V. They stopped the stretcher at the rollers (Photo 67), thus keeping the stretcher from being pushed too far into the muffle, which would have damaged the muffle's rear wall. One stretcher weighed about 51 kilograms. In March of 1943, this system was introduced in Crematorium II as well.

The operation of the coke-fired triple-muffle furnace is detailed in Topf's instruction sheet (Document 227). It is similar to that for the double-muffle furnace. For greater clarity, I have again added – to the translated text and in square brackets – my explanations and/or references concerning relevant photos and documents. Text in rounded parentheses appears in the original text:[477]

> *"Operating instructions for the coke-fired Topf triple-muffle incineration furnace.*
> *Before any coke is fed to the two coke generators* [Photo 158; through the two loading shafts, Photos 160-164]*, the flue-duct damper* [Documents 202b&c] *on the furnace must be opened.*
> *Now fire can be lit and maintained in the two generators; care must be taken to make sure that the secondary covers to the right* [Photo 165] *and left* [Photo 173] *of the ash-removal doors (coke generators) are open.*
> *Once the incineration chamber shows a satisfactory red glow (about 800°C), the corpses can be introduced successively into the three chambers.*
> *At this point, it is advisable to switch on the air compressor located at the side of the furnace* [Photos 188-191] *and to let it run for about 20 minutes. By observation, it must be decided whether too much or too little fresh air enters into the three chambers.*
> *Control of the fresh-air flow is effected by means of the rotary vane* [Photos 192 & 194] *located in the air duct. Furthermore, the air-entry ports to the right* [Photo 148] *and left* [Photo 150] *of the introduction doors must be half-open.*

[477] Topf, *Betriebsvorschrift des koksbeheizten Topf-Dreimuffel-Einäscherungsofen*. March 1943. From: Pressac 1989, p. 222.

As soon as the corpse parts have dropped from the fireclay grate [Photos 145 & 147] *onto the inclined ash plate below* [Photos 131, 134, 140f., 156f.]*, they must be moved forward towards the ash-removal door* [Photo 71] *by means of the scraper. These parts may remain here for another 20 minutes for post-combustion. Then the ash is transferred into the ash container* [Photo 155] *and set aside for cooling.*
In the meantime, new corpses will be introduced successively into the chambers.
The two generators must be refueled from time to time.
Each night the generator grate [Photos 167, 174] *must be freed of coke slag and the ash must be removed.*
It is important, furthermore, that after the end of the operation as soon as the generator has burned itself out and [coke] *embers are no longer present, all air dampers and doors* [of the ash chambers, the gasifiers' loading shafts, the muffles' ash chambers, and the introduction doors]*, as well as the flue-duct dampers, must be closed in order not to cool down the furnace.*
After each incineration, the furnace temperature will increase. Therefore, care must be taken not to let the internal temperature exceed 1100°C (white heat).
This temperature increase can be avoided by feeding air."

The two large-size triple-muffle furnaces (*Groß-Einäscherungsöfen*) originally ordered by the Auschwitz Central Construction Office for the PoW camp at Birkenau, but never built, were structurally different from those set up in Crematoria II and III at Birkenau, as shown by the Topf quotation for these two furnaces dated 12 February 1942 (Document 228):[478]

Cremation furnaces		

Quotation for the supply of 2 triple-muffle cremation furnaces and construction of chimney lining with cleaning port.

Item	*Qty*	*Description*	*Unit pr.*	*Total*
I)	*1*	*Coke-fired triple-muffle incineration furnace* *With the following services and supply:* *The necessary fireclay materials consisting of normal, wedge-type and shaped bricks and monolite tamping material with the corresponding mortar. For the insulation of the furnaces the necessary bricks of diatomaceous earth, rock wool and*		

[478] Topf, *Kostenanschlag* for *Zentralbauleitung* dated 12 February 1942 concerning two triple-muffle cremation furnaces of simplified type. APMO, BW30/34, pp. 27, 32, 29 (sic).

Item	*Qty*	*Description*	*Unit pr.*	*Total*
		diatomaceous-earth mortar.		
		Cast- and wrought-iron fittings such as:		
	3	*Wrought-iron blocking dampers lined with Monolite, including one corrugated-metal plate covering on front side of damper and installation of an observation port,*		
	6	*Cast-iron chain rollers,*		
	6	*Cast-iron bearings*		
	3	*Cast-iron wall cranks for loads of 500 kg each,*		
		The necessary cables and 4 chains for the dampers,		
	10	*Cast-iron air-channel closures,*		
	5	*Cast-iron ash-removal doors, lined with fireclay,*		
	1	*Cast-iron gasifier-loading-shaft closure, with insulating cover,*		
	2	*Cast-iron ash container,*		
	1	*Cast-iron smoke-channel damper sliding in air-tight guide, including rollers, cable and counter-weight,*		
		The necessary stokers for the gasifier,		
		The horizontal grate made of wrought-iron square bars including supporting bars,		
	1	*Wrought-iron coffin-introduction device consisting of a stretcher and 6 pcs. rollers with fixation bar,*		
		Delegation of builder for construction of furnace and of one engineer for hand-over of furnace.		
		Price of Item I) for 1 furnace RM	*7,106.-*	
		Price of Item I) for 2 furnaces RM		*14,212.-*
II)		*<u>The fireclay lining for the chimney</u> up to a height of 6 m, thickness 12 cm:*		
		1,400 normal refractory bricks, Seger Cone 30,		
		700 kg of refractory mortar M 2		
		1 cast-iron manhole for cleaning.		
		Price of Item II) RM		*440.-*
		The anchor bars necessary for the furnace must be manufactured by the client, at no cost to us, as per our drawing. Furthermore, for each furnace, the client will supply, at no cost to us:		
		about 4,000 pcs. bricks		
		6 m³ of construction-type sand		
		1,200 kg of lime		
		500 kg of cement		
		These materials belong to the outer brick casing.		
		For the duration of the job our builder must be		

Item	*Qty*	*Description*	*Unit pr.*	*Total*
		supplied by the client with 3-4 helpers, at no cost to us. *Total authorization-code weight 3,450 kg* *Our prices are ex works, without packing*		

This furnace is characterized by the presence of only one gasifier – the cost estimate, in fact, speaks of only one grate (*Planrost*) and one closure for the loading shaft of the gasifier – and mentions only a single flue duct – there is only one flue-gas damper – and muffle doors running vertically like those in a single-muffle furnace (Document 163).

The parts, as listed in the cost estimate, seem to be those of a furnace with the gasifier located behind the center muffle, as shown by the respective drawing (Document 229): the gases from the generator first flow into the center muffle, then through the openings between the muffles, on into the outer muffles; the spent-gas system could be similar to the one of a single-muffle furnace (Document 229a) or to the system of the Auschwitz-type double-muffle furnace (Documents 229b & 229c). The air-feed system for the combustion air was similar to that of the triple-muffle furnaces at Buchenwald and Birkenau, with their ten closures for the air channels instead of eleven, because the furnace had only a single gasifier.

The fact that five ash-removal doors are listed (instead of four – three for the muffles and one for the gasifier) is explained by the fact that this figure includes the closure for the loading shaft of the gasifier as well, it being identical to the ash-removal doors in this case. This type of furnace had neither a blower nor a draft enhancer. The coffin-introduction device consisted of three pairs of rollers mounted on a bar like the rollers of the Topf 8-muffle furnace (see the next subchapter) and a stretcher as described above.

7.3. The Coke-Fired 8-Muffle Furnace

This furnace was designed by Engineer Prüfer probably towards the end of 1941. Its original concept is described in a Topf cost estimate dated 16 November 1942 (Document 230):[479]

Quotation for one Topf 8-muffle cremation furnace		
#	*Description*	
	<u>Supply and construction of a Topf 8-muffle incineration furnace</u> *including:* *For the outer brick coat* *approx.. 9,000 bricks (normal size)* *approx.. 14 m³ sand, construction type* *approx.. 3,000 kg of building lime* *approx.. 500 kg of cement* *(These materials must be made available to our builders free*	

[479] Topf, *Kostenanschlag über einen Topf-Achtmuffel-Einäscherungs-Ofen* dated 16 November 1942. RGVA, 502-1-313, pp. 72-74.

	of charge).	
	The fireclay materials, viz.: *1,600 wedge-type fireclay bricks, Seger Cone 33/34* *3,000 normal fireclay bricks, Seger Cone 33/34* *1,500 normal fireclay bricks, Seger Cone 32* *3,000 kg refractory mortar M I* *35 fireclay grate bricks, special shape* *35 fireclay plates, special shape* *2,000 kg Monolite caulking mass.*	
	The cast- and wrought-iron fittings, such as:	
4	*Hearths for wood firing consisting of their cast-iron inclined grate, cast-iron flat grates, loading-shaft covers of corrugated metal with reinforcing bars, and the wrought-iron supporting bars for the grates,*	
2	*Cast-iron flue-gas-channel damper running in its air-tight guide, including rollers, cables and counterweights*	
8	*Wrought-iron muffle-blocking dampers with chains and suspension bars (these dampers will be lined with Monolite),*	
10,000	*kg of diatomaceous-earth insulating mass,*	
16	*Cast-iron chain rollers and the necessary cast-iron bearings with wrought-iron shafts,*	
2	*Wrought-iron stokers, consisting of scraper and stoking rods,*	
	The necessary cables, chain and cable rollers as well as counterweights,	
1	*Supporting bars for fixation of cable and chain rollers,*	
4	*Wrought-iron ash boxes with reinforcing bars and 2 handles each,*	
20	*Cast-iron closures for the air channels,*	
8	*Cast-iron ash-removal doors, fireclay lined, with frame and coil handles,*	
2	*Coffin-introduction devices, each consisting of a wrought-iron stretcher, and rollers with their fixation bars for each muffle.*	
	<u>Supply of builder(s)</u> for construction of the furnace, including daily rates, social security contributions and travel expenses.	
	Price of the furnace RM	*12,972.--*
	Authorization-code weight 3,600 kg. *The price is quoted f.o.b. Erfurt Station.* *For the duration of the construction, our builder must be supplied with a sufficient number of helpers at no cost to us. On arrival [of the parts] on site, the foundations must have been made ready by the client. If supervision of the furnace foundation by our builders is desired, we would provide the latter at daily rates at your expense.*	

In the Topf bill of lading (*Versandanzeige*) of 8 September 1942, there is a list of parts for two 8-muffle furnaces (Document 231). The document is translated

below, with the exception of the first two columns, which contain the name of the company and the order number:[480]

Number of cases	*Packing Type*	*#*	*Object*	*weight in kg*	
				net	*gross*
		2	*Complete 8-muffle incineration furnaces consisting of:*		
16	*loose*	*16*	*Cast-iron fire doors 280/350 mm*	*736*	*736*
24	*“*	*24*	*Cast-iron air-channel closures 108/126 mm, Model 311a*	*180*	*180*
16	*“*	*16*	*Cast-iron air-channel closures*	*232*	*232*
4		*4*	*Cast-iron smoke-channel dampers (800 mm high, 700 mm wide) consisting of:*		
4	*“*	*4*	*guides*	*280*	*280*
4	*“*	*4*	*Cast-iron dampers*	*342*	*342*
4	*“*	*4*	*Damper rods*	*8*	*8*
1	*pack*	*8*	*Cable rollers, fig.2*	*13*	*13*
17	*loose*	*17*	*Cast-iron chain rollers, 210 mm segment diameter, bore ∅ 35 mm*	*90*	*90*
16	*“*	*16*	*Muffle-blocking dampers*	*736*	*736*
4	*“*	*4*	*Introduction stretchers*	*204*	*204*
15	*“*	*15*	*Cable roller with support*	*60*	*60*
2	*“*	*2*	*Cast-iron covers, Model 8973 for closing of gasifier-loading shaft*	*23*	*23*
8	*“*	*8*	*Closures for gasifiers*	*252*	*252*
4	*“*	*4*	*Angle bars 60/60/6, each 2,300 mm long*	*44*	*44*
4	*“*	*4*	*Ash receptacle, metal plate*	*24*	*24*
4	*“*	*4*	*Stokers*	*22*	*22*
4	*“*				
			Subtotal		*3,246*
4	*“*	*4*	*Stoking rods*	*13*	*13*
8	*“*	*8*	*Gas piping 2,” each 1,250 mm long*	*44*	*44*

The final invoice, drawn up by Topf on 5 April 1943 (Document 232) lists the parts actually supplied to the Central Construction Office:[481]

Item	*Number*	*Amount*
[Invoice] *concerning supply and services for erection of 2 Topf large-size incineration furnaces having 8 muffles each, viz.:*		
a. <u>Supply</u>		
of normal, shaped and wedge-type fireclay bricks, fire-resistant mortar and fire-resistant Monolite packing mass, additional anchoring bars for damper-suspension and gas-ifier-loading shafts, of cast- and wrought-iron fittings for wood-fired hearths, muffle- blocking dampers with rollers, cables and hand cranks, stokers, ash boxes, ash-removal doors, air channel-closures with their frames, introduction device,		
b. <u>Provision</u> of our builder for construction of furnace		
As per our letter of 8 December 1941 and our letter of 9 December 1941 for 1 furnace	*13,800.--*	
for 2 furnaces		*27,600.--*
Expenses for freight for our shipment of 29 March 1943		*32.30*
Reference: letter with order from Reichsführer SS dated 4 December 1941 II/7/3 Wi/Fl.		*27,632.30*
Payment from Amtskasse *Waffen-SS Posen on 5 May1942 RM 27,600.--.*		

[481] Topf, *Schlussrechnung Nr. 380* for *Zentralbauleitung* dated 5 April 1943. RGVA, 502-1-314, pp. 29-29a.

This list is completed by Topf's Final Invoice No. 322, of 12 July 1944, but back-dated to 23 March 1943 (Document 233) as far as the additional equipment ordered by the Central Construction Office goes:[482]

Item	*Amount*
We supplied on 25 January and on 19 March 1943	
4 cast-iron doors with cast-iron frame, coil handles for fireclay lining	*360*
7,500 kg of rock wool instead of 5,000 insulating bricks and 1,200 kg of rock wool	*1,218*
4 gasifier grates made of square bars 40/40 each 1,200 mm long	*1,680*
	3,258
As per our cost estimate of 2 September and letter of 22 September 1942 concerning your order of 15 September 1942	
Your payment of 2 February 1944 RM 3,258.--.	

As mentioned in Chapter 6, there were actually eight cast-iron closures.

The above documents, the Drawings of the Birkenau Crematorium IV (and hence, of Crematorium V, its mirror image) 1678, 2036 and 2036(p) (Documents 234-236) – which show the foundations and the vertical section of the 8-muffle furnace – the photos of the crematorium ruins taken by the Poles in 1945, as well as an inspection on-site allow us to re-establish the design of this furnace with satisfactory precision. Its overall dimensions can be deduced from the list of anchoring bars etc. drawn up by Topf on 4 September 1942 (Document 237) for the 8-muffle furnace:

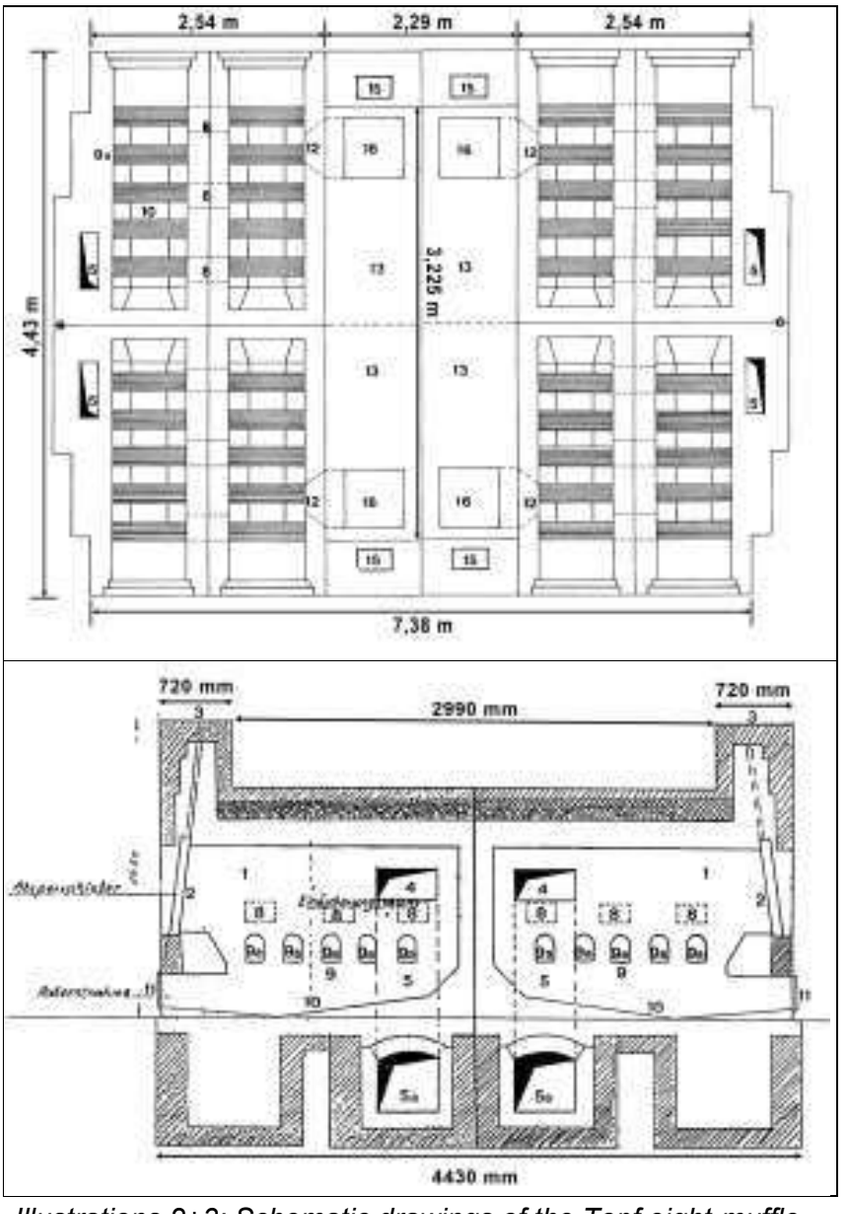
Dimensions of the Auschwitz 8-muffle furnace (see Illustrations 3f.):

Muffle block (each with 2 × 2 muffles; two of them):	
height	2,450 mm
length	4,430 mm
width	2,545 mm
Length of parapet housing the muffle damper	720 mm
Distance between two opposing muffle-damper parapets	2,990 mm
Gasifier block (2 × 2 generators):	
height	2,060 mm
length	3,225 mm
width	2,290 mm

The furnace, including the gasifier, thus measured 4.43 m × [(2.545 × 2) + 2.290 =] 7.38 m.

Judging from the dimensions of the steel bars still apparent at Crematorium V, these overall dimensions of this furnace complex were followed during construction.

[482] Topf, *Schluss-Rechnung Nr. 322* for *Zentralbauleitung* dated 23 March 1943. RGVA, 502-1-327, p. 22.



Illustrations 2+3: Schematic drawings of the Topf eight-muffle furnace; top: cross-section at the level of the muffle grate; bottom: longitudinal section through a lateral muffle (Documents 239 and 240) with dimensions added.

The description which follows is based on the documents mentioned in this section, on the Polish photos of 1945, and on our visual observation of the ruins of Crematorium V. For greater clarity, the description is illustrated by three drawings prepared by ourselves (Documents 238-240). The numbers in parentheses which appear in the description refer to these documents.

The Topf coke-fired 8-muffle furnace was made up of eight single-muffle furnaces as per Topf Drawing D58173 (Document 163) arranged in two groups of four furnaces; each group consisted of two pairs of furnaces opposing each other in such a way that they shared their rear walls and the central walls of the muffles (Document 238) in a manner already used in the Płaszów Crematorium (cf. Document 175). The two furnace groups were connected to four gasifiers coupled in the same way (Document 238, *Generator 1-4*) and thus formed a single 8-muffle furnace, also called "*Großraum-Einäscherungsofen*," literally "large-scale incineration furnace."

The furnace was contained in a solid brick structure by means of anchor and retaining bars still clearly visible on the Polish photos of 1945 depicting the ruins of Crematorium V (Photos 222-225) and still visible half a century later (Photos 228-230).

The muffles (No. 1) had doors (No. 2) weighing 46 kg and running vertically in a frame set into the frontal brickwork (No. 3) above each pair of muffles. The doors were operated by means of pulleys attached to the roof beams, cables and counterweights.

In the outside wall of each of the four outer muffles, in their rear portion, was an outlet for the spent gases (No. 4) leading into a vertical duct (No. 5) in

such a way as to form two parallel pairs of ducts – one for each group of two muffles. Each was housed in a brickwork structure (No. 6) located on either side of the furnace. The two pairs of ducts fed each separately into two horizontal ducts (No. 5a) which merged into a single one (No. 7) with its damper operated by means of a pulley with its cable and counterweight. Each damper measured 0.8 m × 0.7 m and weighed 85.5 kilograms.

The two ducts ran horizontally in opposite directions below the floor of the furnace hall and ended in a chimney, having a square cross-section of 0.8 m × 0.8 m and a height of 16.87 m (photo 233). The flue ducts did not have inspection manholes. The chimneys had no draft enhancers.

The interior wall of each pair of muffles had connecting openings (No. 8), probably three in number as in the double- and triple-muffle furnaces. The rear walls of the muffles were totally closed by refractory brickwork. The floors of the muffles consisted of a fireclay grate (No. 9), probably made up of five fireclay bars as in the single-muffle furnace. In this respect, the information supplied by the bill of lading of 8 September 1942 is unclear, because this document speaks of 60 bars 140 mm × 250 mm × 650 mm and 40 bars 120 mm × 250 mm × 850 mm for a total of 16 muffles, but dividing the total number of bars by the total number of muffles does not result in an integer (100÷16 = 6.25). It is thus likely that this supply item included spare bars. The width of the grate, and hence that of the muffle, must have been 700 mm as in the double-muffle furnace, which had bars of the same length. If the width had been 850 mm, then the 650-mm bars would have been too short. The difference in length between the two different types of bars can perhaps be explained by assuming that the 650-mm bars may have rested on protruding specially shaped bricks at the edge of the ash chamber, whereas the 850-mm bars extended into the muffle wall by 75 mm on either side.

Below the muffle grate was the post-combustion chamber (ash chamber; No. 10) closed at the front end by the ash-removal door (No. 11). This type of door, 280 mm × 350 mm, was the same as used for the gasifier hearths, therefore, in the bill of lading of 8 September 1942, these ash-chamber doors are labeled "*Feuertüren*."

Combustion air was fed to the individual furnaces and to the gasifiers through 20 air channels having an equal number of raisable closures, twelve standard closures (108 mm × 126 mm, weight 7.5 kg) and eight larger ones (14.5 kg) like those mistakenly installed in the side walls of the poorly reconstructed double-muffle furnaces of today's Crematorium I (cf. Photos 87 and 96). These closures were arranged as follows:

– one, standard type, next to the ash-chamber door as shown on Photos 226f. (= 8 closures);
– one, large type, next to the muffle door as on the Topf Mauthausen furnace (= 8 closures);
– four, standard type, next to the gasifier-hearth grate (= 4 closures).

The use of air channels to the muffles larger than those on the two- and triple-muffle furnaces was probably meant to at least partly compensate for the absence of blowers.

On the outer part of the post-combustion chamber was a horizontal air channel running parallel to it and linked to it by means of transverse openings. This channel let out at the front of the furnace, next to the ash-removal door, and was closed by a standard-type raisable cast-iron closure already mentioned. The channel constituted the air feed for the post-combustion chamber.

On the inner sidewall of the post-combustion chamber of the four inner muffles one or two openings were located (No. 12) which were connected to the gasifiers, as in the Gusen Furnace (Photos 16, 27).

The furnace was equipped with two pairs of gasifiers (No. 13) located on opposite sides between the two groups of four muffles. Each pair fed the two muffles next to it.

As far as their lateral position and their connections to the muffles are concerned, the gasifiers were structurally similar to those of the Gusen Furnace (Photo 1): the Auschwitz pair of furnaces plus gasifier on the left compares to the two furnaces plus only the right-hand gasifier of the Gusen Furnace, while the Auschwitz pair of muffles plus gasifier on the right compares to the two muffles and only the left-hand gasifier of the same Gusen Furnace, meaning that at Auschwitz the gasifiers were housed one beside the other in a single brick structure. To visualize it, I have prepared a Foto composition (Document 241), realized on the basis of the Gusen Furnace, which reflects rather well the concept of the eight-muffle furnace and shows clearly to what extent this furnace was inspired by the furnace at Gusen.

As opposed to this, the gasifiers were probably similar to those of the Topf Furnace at Mauthausen (Photos 75, 77f.) with a sloping plate, on which was placed the gasifier-loading-shaft door. Furthermore, the four gasifiers of an 8-muffle furnace possessed a rather light-weight (11.5 kg) "cast-iron lid Model 8973 for closing the loading shaft of the gasifier," whose mechanics are unclear. The service pits (No. 14; Photos 222, 224, 232) – which allowed access to the gasifiers with their loading doors (No. 15) the hearth doors – were located in front of the gasifiers.

The hearth frames were attached to the anchoring bars of the gasifiers by means of two rods still visible in the rubble of the furnace (Photo 230f.). The steps shown on drawings 1678 and 2036 were replaced by a ladder with wrought-iron rungs, visible on Photos 230 and 232.

As I have explained in Chapter 6, the 8-muffle furnace for Mogilev, which were taken over later by the Central Construction Office at Auschwitz had hearths with inclined grates for wood firing (without lids). For the grates of the furnaces shipped to Auschwitz, both inclined and level bars for coke firing were used. The available documents diverge as to the number and the lengths of these bars; it is certain, however, that the throughput capacity of the grates was 35 kg of coke per hour (see Document 264).

The corpse-introduction system consisted of a stretcher for the corpses as described in the preceding section, clearly shown on Photo 222, and by two

rollers of simplified design. These rollers consisted of a metal cylinder rotating around an inside axle which was attached to two vertical bars bolted onto an angled anchoring bar at the level of the fireclay grate of the muffle as shown in Photo 226.

At the two extremities of the cylinder, guide disks were welded, 6 cm wide and 10 cm in diameter, supporting the lateral tubes of the corpse stretcher, and with the entire cylinder rotating around its own axle. Photo 226 shows furthermore four steel servicing tools resting on the anchoring bar of the furnace, and on the ground, below them, several square bars that were part of the gasifier grates.

Originally, 2,500 insulating bricks and 600 kg of rock wool had been foreseen for the insulation of one 8-muffle furnace,[483] but later, as can be seen on the final invoice No. 322 backdated to 23 April 1943 (Document 233), the 2,500 insulating bricks were substituted for by 3,750 kg of rock wool; hence each one of the two 8-muffle furnaces was insulated by 4,350 kg of rock wool.

The brickwork of one 8-muffle furnace was composed of:

– 1,600 wedge-shaped refractory bricks ≈ 5,300 kg
– 4,500 normal refractory bricks ≈ 15,800 kg
– 3,000 kg of refractory mortar,

for a total weight of about 24,100 kg.

Assuming for the four gasifiers a total weight of the brickwork of 8,000 kg, the refractory brickwork of each muffle weighed some 2,000 kilograms. Judging by its flimsy structure, the 8-muffle furnace was the least-reliable of the furnaces built by the Topf Co.

7.4. The Plans for Mass Cremations at Auschwitz-Birkenau

7.4.1. The Furnace Designed by Fritz Sander

In Chapter 3 of this unit, I presented the uncommented translation of a patent application by Fritz Sander dated 4 November 1942 concerning a "Continually operating corpse-combustion furnace for large-scale operation." I will now discuss the significance and the scope of such a device in the light of another document.

On 14 September 1942, the Topf engineer Fritz Sander wrote a letter to the brothers Topf, owners of the firm in which he worked, explaining to them the "new design" of a furnace he had invented. Of this letter, only the first page and some excerpts of other pages have been published (Schüle 2011, pp. 443-447):

> *"The great demand for cremation furnaces for concentration camps which has lately manifested itself especially in the case of Auschwitz and which has, according to the report by Herr Prüfer, led to a further order for 7 triple-muffle furnaces,*[484] *has prompted me to look into the question of whether the concept*

---

483 Letter from *Zentralbauleitung* to Topf dated 15 September 1942. RGVA, 502-1-312, p. 22.

484 We can see from K. Prüfer's note of 8 September 1942 (cf. Subchapter 8.2) that besides the five triple-muffle furnaces of Birkenau Crematorium II, the *SS-WVHA* had ordered another three 8-muffle furnaces, but still, the number of muffles was insufficient. Actually, for Crematorium III, another five triple-muffle furnaces were ordered, and another two for the crematorium at Gross-Rosen, so twelve

of muffle furnaces used so far at the places mentioned is indeed the most-suitable one.
In my opinion, in a muffle, the cremation does not proceed quickly enough to ensure the elimination of a great number of corpses at a desirably high rate. As a makeshift solution, one has tried to use a series of furnaces or muffles and by loading them with more corpses, but this does not solve the basic problem, i.e. the drawbacks of the muffle system. These drawbacks of the muffle furnace, which cannot be solved even by assembling more muffle furnaces (triple- or 8-muffle furnaces) and loading more corpses into an individual muffle, are in my judgment the following:

1) Discontinuous operation.
Each muffle, at regular intervals, must be loaded, cleaned, then loaded again and cleaned again, and this goes on for the [whole] *duration of the operation of the furnace. Each time* [a cremation is undertaken] *it is necessary to open the introduction door at the front, and the corpses must be loaded into the muffle through this front door. While this goes on, cold air flows into the furnaces, cooling the muffle, which not only reduces its service life, but also causes heat losses which have to be made up by additional fuel.*

2) Problems of introduction.
In any case, it is difficult and unpleasant work to insert the corpses into the muffle in the longitudinal direction, especially if several corpses have to be packed into the muffle at the same time. In the long run, it will also be impossible to avoid damaging the delicate muffle masonry.

3) Large space requirement of the multi-muffle furnaces.
In terms of floor space, the multiple-muffle furnaces take up quite a bit of room and require a considerable amount of material for their construction. Moreover, the corpses to be cremated have to be transported each time in front of the opening of the respective muffle, i.e. they have to be distributed over a number of such places. They are thus scattered over the entire floor space of the cremation room. The same applies to a certain extent to the fuel.
To overcome the above disadvantages, and in my opinion as the ideal solution with regard to the design of a cremation furnace for the purpose of a concentration camp, I consider a furnace with continuous loading and also continuous operation."

This is followed by a discussion of the options for such a continuously operating furnace and a detailed description of a furnace which over wide areas reads like an anticipation of the later patent application (see Document 242). After describing the furnace he had invented, Sander continued:

"I realize very well that this kind of furnace must be considered a mere device of destruction and that one has to cast aside all considerations of piety, separation of the ashes, or any sentimental factor. But all this is already with us in the case of multi-muffle furnaces. After all, we have special conditions in the concentration camps due to the war which force [us] *to adopt such a procedure.* […]
In view of the considerations set out above, it is to be assumed that the authorities in charge will also approach other furnace manufacturers for the supply of

in total.

> *cremation furnaces functioning quickly and well. These* [firms]*, too, will look for the best design of furnaces for the applications mentioned. I must therefore assume that this question is now being addressed by all sides, and that ideas for new types of such furnaces are thus emerging in other furnace-construction companies as well. For this reason, I believe it to be urgent to apply for a patent for my proposal in order to protect our priority."*

This patent application concerning a "cremation furnace for corpses in continuous operation for mass application" was drawn up by Sander on 26 October 1942, and then revised by him on 4 November 1942. The patent application of 4 November 1942 confirms Sander's ideas as described in the letter of 14 September 1942:

> *"The collection camps in the occupied eastern territories set up on account of the war and its consequences with their inevitably high mortality do not permit the interment of the large number of deceased camp inmates. There is, on the one hand, a shortage of space and labor, and, on the other, the risk of exposing the vicinity, near or far, to the dangers presented directly or indirectly by any burial of the deceased, many of whom have succumbed to infectious diseases.*
> *The need thus exists to eliminate safely, quickly, and hygienically the corpses generated continuously in large numbers."*

Sander explained that this task could not be accomplished in accordance with the legal requirements applicable within the Reich territory, for it imposed the need to burn such corpses jointly and concurrently, with the flames and combustion products striking the corpses directly throughout the entire process; thus, one could not speak of a proper *cremation* but rather only of a *combustion* of the corpses. He continued:

> *"For the execution of this combustion – in line with the viewpoints exposed above – in some of these camps multiple-muffle furnaces were erected which obviously had to be loaded and operated serially. For this reason, these furnaces are not entirely satisfactory, as the combustion in them does not proceed quickly enough to permit the elimination of the large number of corpses generated continually within a short period of time."*

Sander's design was nothing but an adaptation of Topf's waste incinerator "*Müll-Verbrennungsofen MV*," which was practically copied from Kori's "*Ofen mit doppelten Verbrennungskammern*" (Furnace with two combustion chambers).[485] The idea of a vertical cylindrical combustion chamber, on the other hand, was taken from the patent of Adolf Marsch, which I discussed in Chapter 10 of Unit I (Documents 96 & 96a).

The reference to the "multi-muffle furnaces" is clearly to Topf's own double-, triple- and eight-muffle furnaces already built at Auschwitz, Buchenwald and Mogilev. The reference to high mortality in the "collection camps in the occupied eastern territories" and of the corpses who "have succumbed to infectious diseases" concerns the concentration camps, Auschwitz in particular, where mortality was extremely high because of the typhus epidemic ravaging the camp at that time.

---

[485] Cf. Chapter 11 and Document 225a&b.

What is most-significant in the patent application and the letter mentioned above is that the very inspiration for the new design was the fact that Topf's chief engineer rated the mass cremation in multi-muffle furnaces – of which Topf was the only manufacturer – to be rather unsatisfactory.

7.4.2. Crematorium VI

In early 1943, Topf elaborated two mass-cremation devices for Auschwitz-Birkenau. A letter written by the head of the Auschwitz Central Construction Office, *SS Sturmbannführer* Bischoff, to the camp commandant, *SS Obersturmbannführer* Höss, dated 12 February 1943, explains the idea of "Crematorium VI" in the following way (Document 243):[486]

> *"With reference to the discussion of the undersigned with engineer Prüfer of Topf & Söhne Co. on 29 January 1943, the project of a sixth crematorium (an open combustion chamber 48.75 by 3.76 m) was considered. The Central Construction Office had therefore requested Topf & Söhne Co. to prepare a sketch of this open combustion chamber, which is attached.*
> *If the construction of this sixth crematorium were to be undertaken, it is requested to forward the respective application to Office Group C via Office Group D.*
> *In case of a possible realization of this installation, more manpower than presently employed must be provided by the command. For this, one would require:*
> *150 detainee bricklayers*
> *200 detainee helpers*
> *The realization of the building project depends on the availability of the manpower mentioned above."*

The sketch of the device has not been preserved. In my opinion, the design of Crematorium VI was based on F. Siemens's field furnace described in Chapter 10 of Unit I. In the Siemens drawing (Document 93) the width of the installation (Section C-D) was about 3.90 m, the length about 5.50 m; the thickness of the walls, Section a-b, was about 35 to 40 cm, the internal dimensions about 3 m × 4.80 m. The "open combustion chamber" of the Crematorium VI Project measured 48.75 m × 3.76 m, which corresponds to a Siemens field furnace of the same width but 10 times longer, *i.e.* of the following dimensions:

- width: 3 m (clear width) + 2 × 0.38 m (outside walls) = 3.76 m.
- length: 10 m × 4.80 m (clear space) + 2 × 0.375 m (outside walls) = 48.75 meters.

The use of bricks for this furnace was an option, but engineer Prüfer could have simplified matters by placing the corpses directly on the grates constituting the top part of the hearth. Separating the individual hearths as in the Siemens furnace, Crematorium VI would have had 60 hearths with a usable surface of 144 square meters, sufficient for the concurrent cremation of some 150 corpses.

---

[486] Letter from *Zentralbauleitung* to the camp commandant dated 12 February 1943. APMO, BW 30/34, p. 80.

7.4.3. The Annular Incineration Furnace

Topf's letter to the Central Construction Office of 5 February 1943 ends as follows:[487]

> *"You will receive the cost estimate for the large ring incineration furnace on Tuesday of next week at the latest. In case a purchase is planned, we kindly ask for an order to be placed soonest to enable us to order the cast-iron and wrought-iron parts right away or start with their fabrication* [ourselves]*."*

A ring furnace (*Ringofen*) is usually used for the sintering of bricks, laid out as shown in Document 244. It consists of a ring-shaped sintering channel (*Brennkanal*), some 2 to 4.5 m wide, 2.5 m high and 60 to 120 m long, into which the material to be sintered is placed. Heating is effected by means of hearths with grates, until the material becomes incandescent. The spent gases leave the sintering channel through flue ducts below, flow into a collection channel and then on into a smoke duct, which takes them into the chimney.

Some 12 to 20 openings are arranged in the side walls of the furnace for the loading and removal of the material to be sintered. The sintering channel is divided into an equal number of chambers linked to one another. The actual sintering takes place in two or three chambers, whereas in the others there is a progressive preheating in one direction and a gradual cooling in the other.[488]

Because of the structure and the technical characteristics of such a device which, among other things, operated intermittently, and also because such a device had never been manufactured by Topf, we may exclude that the "ring incineration furnace" suggested by Topf was of this type. The designation would rather refer to the "cremation furnace for corpses in continuous operation for mass application" devised by Fritz Sander with its cylindrical combustion chamber.

7.4.4. The Furnace of the Quotation Dated 1st April 1943

Another project for a mass cremation device appears in a Topf cost estimate, of which R. Schnabel presents only the last page (Document 245; Schnabel 1957, p. 351):

J.A. Topf & Söhne *Quotation of 1 April 1943 for Auschwitz*		
reg. no.	#	*Object*
	1	*Cast-iron damper for smoke channel with rollers, metal cable and hand crank,* *The necessary stokers.* *Provision of builders for construction of the furnace including travelling expenses, daily rates, and social security contributions.* *Price of furnace: RM 25,148.--* *Weight for authorization code: 4,037 kg*

[487] Letter from Topf to *Zentralbauleitung* at Auschwitz dated 5 February 1943. APMO, BW AuII 30/4/34, D-Z-Bau/2544/2 (illegible page number).

[488] *Hütte* 1938, vol. IV, pp. 739f.

		For the duration of the construction our builders must be supplied with a sufficient number of helpers at no cost to us. *All construction materials such as bricks, sand, lime and cement must be provided at the site in time; these materials must likewise be supplied at no cost to us.* *They concern:* *about 19,000 bricks* *about 20 m³ of sand* *about 800 kg of cement* *about 6,000 kg of lime.* *Our price is given FOB railway freight car at station* *By order. J.A. Topf & Söhne* *signed: Sander, Erdmann.*

We do not know where the original of this document might be. When comparing it to the known Topf estimates, we see that it is the last page of an estimate: there is no letterhead of the firm, no addressee, no description of the device, and the data which do appear are those normally shown at the end of estimates. It is certain, in any case, that the furnace described in this estimate was a real cremation furnace, even if of a special type. The presence of a flue-duct damper (*Rauchkanalschieber*) leaves no room for doubt in this respect.

A comparison of this device with the constituents of the 8-muffle Mogilev Furnace shows that it was an even-bigger furnace:

	8-muffle furnace	Furnace of estimate of 1st April 1943
Bricks	9,000	19,000
Sand	14 m³	20 m³
Lime	3,000 kg	6,000 kg
Cement	500 kg	800 kg
Metal	3,600 kg	4,037 kg
Price	12,972 RM	25,148 RM

The comparison shows that the number of bricks for the outer facing of the furnace in question was twice as large as that of the 8-muffle furnace, and one may thus suppose that the outer surface also was roughly twice the size.

The enormous price difference between the two devices, even if the weight of the metal is not very different, can probably be explained by a most-relevant difference in weight for the refractory and the insulating material and would hence confirm the gigantic dimensions of this furnace. These dimensions agree much better with a special furnace such as the one invented by Fritz Sander which, incidentally, also had only one smoke duct.

The devices described in this section were never built, probably because conditions had changed. In January of 1943, the Birkenau crematoria were still being erected; by the end of March, Crematoria II and IV were in operation, with Crematorium V joining them in early April.

The cost estimate of 1st April 1943 certainly responded to a request by the Central Construction Office made a few weeks earlier when the sanitary situa-

tion in the camp was disastrous because of a resurgence of the typhus epidemic which had struck the previous year. Between 2 March and 1st April of 1943, a total of 7,300 detainee deaths were recorded in the *Sterbebücher*.[489] From April onwards, mortality went down considerably, and that is probably the reason why the Central Construction Office abandoned these projects.

8. The Duration of the Cremation Process in the Topf Furnaces at Auschwitz-Birkenau

8.1. The Documents

In this chapter, we will consider the controversial question of the cremation capacity of the Topf furnaces from the point of view of the duration of the process. There are four documents on this topic, which, however, yield rather diverging data.

In the Topf letter sent to the New Construction Office of *KL* Mauthausen on 1 November 1940, with an attachment of a cost estimate concerning "one coke-fired Topf double-muffle cremation furnace, with compressed-air system" as well as one concerning a "Topf draft-enhancing device" (Document 194), we read:[490]

> *"Our Herr Prüfer had already informed you that in the furnace previously proposed* [on 31 October 1941] *two corpses per hour can be incinerated."*

As we are dealing here with the Auschwitz-type double-muffle furnace, Prüfer's statement refers to the cremation of one corpse in one muffle in one hour. This corresponds to a theoretical cremation capacity of 48 corpses in 24 hours.

A few months later, on 9 July 1941, the SS New Construction Office at *KL* Mauthausen sent Topf the following request:[491]

> *"This office asks to be informed about the number of cremations which may be carried out in one furnace per day without danger to the equipment (coke-firing). Furthermore, we ask you for the supply of 2 service instructions for the furnaces."*

Topf replied on 14 July by the following letter (Document 247):[492]

> *"Re: Your letter of 9 July 1941. Cremation furnace.*
> *In pursuance of our* [sic] *letter mentioned above we are sending you the requested instructions in triplicate and ask you to exhibit one at a visible spot close to the furnace hall. The other two may be placed in your files.*
> *In the Topf coke-fired double-muffle cremation furnace, 30-36 corpses can be cremated in about 10 hours. This number may be cremated daily without undue strain on the furnace. It is not harmful either to carry out cremations day and*

---

[489] Staatliches Museum… 1995, Vol. I, p. 236.
[490] Letter from Topf to *SS-Neubauleitung* at Mauthausen dated 1st November 1941. BAK, NS 4/Ma 54. Cf. Document 246.
[491] Letter from Topf to *SS-Neubauleitung* at Mauthausen dated 9 July 1941. BAK, NS4/Ma 54.
[492] Letter from Topf to *SS-Neubauleitung* at Mauthausen dated 14 July 1941. SW, LK 4651.

night, one after the other, if operations require this. It is a fact that the refractory lasts longer if a uniform temperature is constantly maintained in the furnace. We hope to have been useful to you in the best way in this matter and salute you
Heil Hitler
By proc. J.A. Topf & Söhne
Sander, Erdmann."

On the basis of what is said in this letter, the duration of one cremation in one muffle would have been some 33 to 40 minutes, and the theoretical capacity of the furnace would therefore have been 72 to 86 corpses per 24 hours.

The third document is the following letter, dated 28 June 1943 and sent by the head of the Auschwitz Central Construction Office (*SS Sturmbannführer* Bischoff) to the head of Office Group C of *WVHA* (*SS Brigadeführer* Kammler; Documents 248, 248a):[493]

"28 June 1943.

31550/Ja./Ne.–

Re: Completion of Crematorium III
Reference: none
Attachments: -/-

To the

SS Economic-Administrative Main Office, Head of Office Group C
SS Brigadeführer and Major General
Dr.-Ing. K a m m l e r
Berlin – Lichterfelde – West
Unter den Eichen 126 – 135

I [hereby] *inform you of the completion of Crematorium III on 26 June 1943. Therefore all crematoria ordered have now been completed.*

Performance of the crematoria presently existing over an operating period of 24 hours:

1.) old Crematorium I	
3 x 2-muffle furnaces	*340 persons*
2.) new Crematorium at PoW Camp II	
5 x 3-muffle furnaces	*1440 persons*
3.) new Crematorium III	
5 x 3-muffle furnaces	*1440 persons*
4.) new Crematorium IV.	
8-muffle furnace	*768 persons*
5.) new Crematorium V.	
8-muffle furnace	*768 persons*
at 24-hour operation a total of	*4756 persons*

The Head of Central Construction Office
of the Waffen-SS and Police Auschwitz.
SS Sturmbannführer."

[493] RGVA, 502-1-314, p. 14a.

Thus, on the basis of this document, the average duration of one cremation was 25 minutes in the double-muffle furnace, and 15 minutes in the furnaces with three or eight muffles.

The fourth document is an internal memo (translated below) written by Engineer Prüfer, dated 8 September 1942:[494]

"TOPF
To: J. A. TOPF UND SÖHNE *Erfurt, 8 September 1942*
Department D IV
Our reference: D IV/Prf./hes
Concerning: Reichsführer SS, Berlin-Lichterfelde-West.
Subject: Crematorium-Auschwitz.
Confidential! Secret!
8 September 1942: Obersturmführer *Krone called and informed us that he has to report to* Brigadeführer *Kämmer* [Kammler] *and that he has to give an account of his visit to the Auschwitz Crematorium, from which he came back yesterday. He has not been told anything about the Auschwitz installation and would therefore like to know exactly how many muffles are presently in operation and how many muffle furnaces we are presently building for forthcoming delivery.*
I explained to him that 3 furnaces with 2 muffles are now in operation with a [cremation] *capacity of 250* [corpses] *per day. Furthermore, 5 furnaces with 3 muffles are now under construction for a* [cremation] *capacity of 800* [corpses].
Today and over the next few days the 2 furnaces with 8 muffles will be shipped, taken from the Mogilev [job], *with a* [cremation] *capacity of 800* [corpses] *each. Herr K. declared that this number of muffles was still insufficient; we are to supply yet more furnaces as soon as possible. It is therefore advisable for me to go to Berlin on Thursday morning to discuss with Herr Krone any further orders. I am to bring with me documents concerning Auschwitz so that these urgent calls would stop once and for all.*
I have announced [my] *visit for Thursday."*

If we follow this document, the average duration of a cremation in the double-muffle furnace was 34 to 35 minutes, in the triple-muffle furnace 27 minutes and in the 8-muffle furnace 14 to 15 minutes. The corresponding cremation capacities of each type of furnace were about 83, 160, and 800 corpses per 24 hours, respectively.

Summarizing, the capacities claimed in these four documents are as listed in the following table, with the time given in minutes and the capacity in corpses per muffle and per 24 hours of operation per day:

Furnace	Document 1		Document 2		Document 3		Document 4	
	time	capacity	time	capacity	time	capacity	time	capacity
two muffles	60'	24	33-40'	36-44	25'	57	34-35'	42
three muffles					15'	96	27'	53
eight muffles					15'	96	14-15'	100

[494] K. Prüfer's memo of 8 September 1942. *EMS/Erfurter Mälzerei- und Speicherbau*, 241, II 80 Tech. Abteilung D IV. Published online at: http://veritas3.holocaust-history.org/auschwitz/topf/. Cf. Document 249.

It is obvious that at best only one of these numbers can be correct.

The first document stems from the copious correspondence between Topf and *KL* Mauthausen, held at the *Bundesarchiv* at Koblenz; the second one was originally part of this correspondence, but it is no longer there, having been transferred to the Weimar *Staatsarchiv*. It is unclear how the document arrived at the Weimar *Staatsarchiv*, which is all the more strange, as it is not Topf's own filed copy but the original of the letter directed to Mauthausen, as we can see from the *in* stamp it bears.

The photocopy sent to this author (Document 247) shows, on the left, several vertical lines whose ink has faded; on the lower-left-hand corner we have, attached to the sheet, a slip of paper with the hand-written entry "in 1943, up to 300 corpses were burned in such a [*im gleichen*] furnace in 10 hours." The author of this hand-written remark is unknown; the remark must, in any case, be considered worthless from a technical point of view and false from a historical point of view. Actually, the incineration of 300 corpses in 10 hours in a double-muffle furnace is equivalent to a time of 4 (four) minutes for each cremation, which is technically impossible. On the other hand, the "such a furnace," *i.e.* the double-muffle furnace, Auschwitz Type, had not yet been installed at Mauthausen in 1943. The authenticity of the typed letter is not in doubt, but the hand-written note was certainly added to it after the war.

The third document, which comes from the Moscow Archives, presents serious problems of form and content which will be treated in Subchapter 9.6.

The fourth document was discovered by Jean-Claude Pressac in 1995 during a search of the archives of the firm *EMS / Erfurter Mälzerei- und Speicherbau*, successor to *Topf & Söhne* at Erfurt. After Pressac's death, part of the documentation on this company which he had collected, including the documents from the above archives, were donated, as he had wished, to the *Thüringisches Hauptarchiv* at Weimar, where it is now held.

In our effort to judge the factuality of the data given in these four documents, and to ascertain the average duration of a cremation in the Topf furnaces at Auschwitz-Birkenau, we shall use three objective criteria, all based on practical conditions: the results of the experimental cremations with coke carried out by R. Kessler on 5 January 1927, a fragment of the list of cremations in the crematorium of the Gusen Camp, and the numerous fragments of such lists concerning the crematorium at the Westerbork Camp (Netherlands).

A further important experimental criterion is provided by the experiments with the incineration of animal carcasses and offal from slaughterhouses run on Kori furnaces. The technical assessments carried out by the Soviets and the Poles on the Majdanek (August 1944), Sachsenhausen (June 1945) and Stutthof Furnaces (May 1945) have yielded still more useful indications.

The lists of cremations in the crematorium of the Terezín Ghetto – which was equipped with four oil-heated Ignis-Hüttenbau furnaces, undoubtedly the most-productive of all the furnaces built during the Second World War – provide us, finally, with an essential benchmark allowing us to set the lower limit of the cremation time achievable in plants operated in German concentration camps and ghettos in the 1940s (see Subchapter 11.4.).

8.2. Richard Kessler's Cremation Experiments

As we have explained in Chapter 6 of Unit I, the duration of the cremation process involving one corpse depends essentially on the constitution and the chemical composition of the body, but – to a not-irrelevant extent – also on the furnace system and the operational procedure of the cremation.

Since the Auschwitz-Birkenau furnaces had a coke-fired gasifier, the experiments carried out by the engineer Richard Kessler in the Dessau Crematorium on 5 January 1927 can be used as a yardstick, if we want to understand how the cremation process unfolded in the furnaces of Auschwitz-Birkenau (cf. Chapter 4 of Unit I). However, if we want to stay in line with actual conditions, we must look at the design differences between the Gebrüder Beck Furnace used by R. Kessler and the Topf double-muffle furnace, Auschwitz Type, the furnace which resembled most-closely the furnaces for civilian use.

The Beck Furnace had a refractory mass of at least 12,000 to 13,000 kg, which allowed for a considerable amount of heat to be stored in the walls, and which reduced the temperature fluctuations during the cremation. The Topf Furnace had a refractory mass of some 10,000 kg, *i.e.* 5,000 kg per muffle and gasifier, hence they stored less heat, which in turn led to more-pronounced temperature fluctuations.

On account of its recuperator, the Beck Furnace possessed an efficient system of preheating the incoming combustion air to high tempertaures, which supported supported the mixing process of the combustion air with the combustible gases coming from the gasifier and from the decomposing corpses, thus reducing the amount of Excess Air and increasing the combustion temperature. Furthermore, the recuperator supported the post-combustion of the heavier hydrocarbons leaving the cremation chamber uncombusted, thus returning part of their heat to the furnace.

The Topf Furnace had no recuperator and no preheating system and thus worked with an air-feed system which had already been tried out in the 1930s and had been found unsatisfactory from the point of view of heat economy. Here, the cold air entered the muffle through four openings set into its vault and was fed into both muffles by means of a single blower, which did *not* allow controlling the air-feed to individual muffles (cf. Schläpfer 1938, p. 155).

The Beck Furnace, moreover, could be switched over to a smoke-combustion mode which reduced the heat loss through otherwise-uncombusted gases and thus attenuating a corresponding reduction of the muffle temperature at a point in the process at which the Topf Furnace (having no smoke-combustion mode) experienced a more-pronounced temperature drop in the muffle (and concomitant greater formation of smoke).

Both furnaces worked with direct combustion, allowing the combustion products of the gasifier to enter the muffle.

We will now consider the results of Kessler's cremation experiments, which I have summarized in Documents 250f. On average, the initial temperature of the cremations was around 800°C (Column 2); the maximum temperature during the combustion of the coffin was around 1,000°C (Column 3), the tempera-

ture at the start of the combustion of the corpses was around 780°C (Column 5), and the maximum temperature during the combustion of the corpses wass around 900°C (Column 7). As far as the durations are concerned, the average time taken for the temperature to reach its maximum after the coffin had been introduced was 12 minutes, the average time for the evaporation of the corpse water was 27 minutes, and, finally, the average time taken for the combustion of the corpses to reach the highest temperature was 28 minutes, whereas the average duration of the entire process up to the second peak temperature was 55 minutes.

Here we must underline the fact that the above times taken for the coffin and for the corpse to be consumed, respectively, are merely measured up to the point where the highest temperature is reached. In both cases, the combustion obviously continues even after the peak temperature has been reached, albeit at a lower rate (Document 251). This is why we have taken 55 minutes to be the average duration of the entire combustion process in Documents 250f., whereas in Kessler's experiments it was taken to be 86 minutes. Hence, even after the most-active combustion phase of the corpses, the combustion process continues for another 31 minutes.

These considerations are important because the Topf cremation furnaces at Auschwitz-Birkenau, or more-precisely their method of operation, was different from Kessler's: on account of both professional ethics and legal requirements as discussed in Chapter 8 of Unit I, Kessler no doubt waited for the ashes to stop burning before moving them into the ash chamber; as opposed to this, the operating guidelines for Topf's furnaces at Auschwitz-Birkenau allowed for the introduction of the next corpse as soon as the remains of the former corpse had fallen through the muffle grate. Thus, the duration of a cremation in the Topf furnaces ended once the remains of the corpse had fallen through the muffle grate bars into the post-combustion (or ash) chamber, where they would go on burning for another 20 minutes, as indicated by the operating instructions.

In both furnaces, however, combustion of the corpses took place primarily within the muffles.

When we look at the chart summarizing Kessler's experiments (Document 251), we see that at the very moment when the combustion temperature of the corpses reached its maximum, *i.e.* after 55 minutes, the corpses themselves were still in the muffle, as is borne out by the fact that the muffle temperature continued to rise as high as 900°C. Therefore, the duration of the combustion process in the muffle up to the point where the remains of the corpse fall through the grate bars into the ash chamber was necessarily longer than the 55 minutes.

When comparing Kessler's cremations and those carried out in the Topf double-muffle furnace at Auschwitz, we must take two more relevant points into consideration:

First of all, cremations in the Beck Furnace were done with coffins, whereas at Auschwitz the corpses entered the muffle unboxed.[495] The coffin has a negative (*i.e.* lengthening) effect on the duration of the cremation, because, for sev-

[495] At the beginning of WWII, the use of coffins was provided for. Cf. Chapter 12.

eral minutes until it breaks down under the heat, it acts as a heat shield for the corpse, thus delaying the evaporation of the corpse water. But after the coffin has broken down, it has a positive effect and speeds up the evaporation process of the corpse water, because the burning wood increases the muffle temperature. Finally, part of the heat contributed by the combustion of the coffin accumulates in the muffle walls and is released again when the thermal conditions in the muffle allow this. This contribution, though, becomes ever-less-significant as the refractory mass of the muffle increases.

Second, the Beck Furnace possessed all measurement devices needed for a continuous observation of the cremation process at any moment of the cremation, and the cremations were carried out under the eye of an expert engineer, and were thus performed in the best possible manner.

From the first, negative, effect we may draw the following conclusion: since the maximum temperature of the coffin's combustion was reached after 12 minutes, we may assume that the evaporation of the corpse water began after some 5 to 6 minutes, which means that the cremation of a corpse without a coffin would take about 50 minutes up to the maximum of the main combustion phase.

In Kessler's cremation experiments, the minimum duration of the cremation process up to the high point of the main combustion phase – 40 minutes – was registered for the last two cremations; the average duration and the temperatures reached in the individual phases were as follows:

– from the moment of introduction (at 805°C) up to the highest temperature (1015°C) reached during the combustion of the coffin: about 14 minutes;
– from the introduction until the end of the desiccation of the corpse (810°C): 30 minutes;
– from the end of the desiccation up to the highest temperature reached during the combustion of the corpse (955°C): 40 minutes.

As the combustion of the coffin reached its highest point after 14 minutes, we may assume that vaporization of the corpse water begins after six to seven minutes, which brings us to a minimum duration of the main combustion phase under optimum conditions of 32 to 33 minutes.

In modern furnaces, the main combustion phase lasts about 30 to 40 minutes.[496] On this point, the engineer L.G.A. Leonard of the French company Tabo, manufacturer of cremation furnaces, gave an account of his experiments at the meeting of the Cremation Society of Great Britain in 1975, saying (Jones 1975, p. 83):

> *"After about half an hour, whether the furnace has got up to a temperature of 1,100° C or whether it is 900° C, there is a rapid fall away, and I think the investigations should be concerned with the last twenty minutes or so of the cremation cycle. At that time you have in the cremator a very very small quantity of body material in the shape of chest and lung material, roughly the size of a rug-*

[496] *I.e.* the time from the introduction of the corpse into the muffle up to the end of the main combustion phase.

by football, about twenty minutes from the end of the cremation, and this is the thing which is most-difficult to remove."

A chart summarizing the phases of the cremation process in a modern crematorium attributes 34 to 38 minutes to the duration of the main combustion (cf. Document 252).

However, actual experiments show longer durations. In the 1990s, Michael Bohnert *et al.* observed fifteen cremations carried out in a modern *Etagenofen* (multiple-hearth incinerator) as part of a study in forensic medicine (Bohnert *et al.* 1998). The gas-fired furnace had a cremation chamber with a post-combustion chamber underneath. The latter had a rotatable grate. The ash chamber was located further below.

The corpses concerned were those of seven men and eight women, between 68 and 100 years of age. The cremation process was observed through a viewing port 13 cm × 11 cm set into the muffle. The phenomena occurring during combustion were recorded at intervals of 10 minutes. The average duration of a cremation in the muffle (main combustion) was about one hour,[497] after which the remains were moved into the post-combustion chamber, where they burned out over another hour.

After 30 minutes, the skull and the trunk were still recognizable: the thorax was open, and the internal organs could be seen (cf. Document 253). After 40 minutes, the ribs had lost their soft tissue, and the base of the skull was visible (cf. Document 254). After 50 minutes, combustion was still intense, and the appearance of the corpse was as follows (*ibid.*, p. 16):

"The facial bones had mostly disintegrated. The base of the skull was visible. The upper parts of the spinal column tended to extend. The vertebrae were calcined and the disks between the vertebrae were missing. The shape was maintained primarily by the remains of the strongly deformed neck muscles. The internal organs, meanwhile, showed a considerable shrinkage. In most cases, only the liver was still recognizable, even though it had been reduced to a sponge-like structure. The soft tissue of the basin which had been protected for a long time had now been consumed by the fire, and the iliacus presented only sparse remains of carbonized soft tissue adhering to the bone. The arms had been completely destroyed. The upper thighs had been reduced to calcined bone stumps."

The cremation in the muffle went on for another 15 minutes on average.

In conclusion it may be said that, as a reference point, the duration of the main combustion phase is about 50 minutes.

8.3. The List of Cremations in the Gusen Crematorium

Among the few documents concerning the crematorium at the Gusen Camp to have been preserved, there is a record drawn up by *SS Unterscharführer* Wassner, head of the crematorium, which lists the number of detainees cremated, and the corresponding consumption of coke, for the period of 26 September

[497] Bohnert *et al.* 1998, p. 12. From Table 1 shown on this page we obtain an average duration of 66 minutes. The average temperature in the muffle was about 750°C.

through 12 November 1941.[498] The list contains four columns. The first column shows the time; next to it we have the number of cartloads of coke supplied. The second column gives the date of the cremation, the third the number of corpses cremated, and the fourth the total number of cartloads of coke (1 cartload = 60 kg). The coke figures in the first column are listed cumulatively, so that the last figure in the first column is the same as the figure in the fourth column.

The document poses some problems, though:

1. Does the date column really indicate the days on which the cremations were carried out? At three points (entries for 31 October, 7 November, and 8 November) the cremations cycle into the early hours of the following day, hence rather than speaking of cremation *days*, we should rather speak of cremation *cycles* or *series*. Each cycle comprises the number of corpses shown in the record and may extend into the following calendar day.
2. Does the number of coke cartloads registered in the first column correspond to the coke *loaded* into the generators at the hour indicated? This possibility must be discounted for the following reason: 1 m³ of loose coke has a weight of 380 to 530 kilograms (*Hütte* 1931, vol. I, p. 718). Let us assume the maximum value of 530 kilograms.

   The two gasifiers at Gusen had a flat grate of 50 cm × 50 cm, like the Auschwitz double-muffle furnace. The loading port of the gasifier stood at a level of 80 cm above the grate. The effective volume of one gasifier was thus 0.5 m × 0.5 m × 0.8 m = about 0.2 m³, which means that each gasifier could load (530×0.2=) 106 kg of coke, *i.e.* 212 kg for both gasifiers. Now, in the above record, the first figure in the first column is, in several cases, between 11 and 16, or between 660 to 960 kg of coke, but in order to take in (960÷2=) 480 kg of coke, each gasifier would have had to have an effective volume of about 1 m³; hence the number of cartloads of coke does not refer to the coke loaded into the gasifiers for the hour indicated.
3. Does the number of coke cartloads shown in the first column refer to the coke *consumed* up to the hour indicated? This hypothesis must be excluded as well, because, for 11 November, at 8:00 PM, 23 cartloads of coke are mentioned (=1,380 kg). The following entry, at 9:20 PM, speaks of 32 cartloads (=1,920 kg). Hence within the 80 minutes between the two entries (1,920 – 1,380=) 540 kg (or 405 kg per hour) would have been consumed, a technically impossible amount. The same reasoning also applies to other cycles, *e.g.* for 6 November we have 600 kg of coke between 10:25 and 14:45 hours, *i.e.* over 4 hours and 20 minutes, or 138 kg/hr, for 7 November: 420 kg of coke between 3:30 and 5:00 AM, *i.e.* over 90 minutes = 280 kg/hr; for 12 November: 420 kg of coke between 15:20 and 18:15 hours, *i.e.* over 175 minutes = 144 kg/hr; etc.
4. Do the times shown in the first column refer to the *beginning* (first figure) and to the *end* (last figure) of the cremations carried out on that day? This question is closely related to the preceding one. If the first figure really re-

[498] Cf. Document 255; ÖDMM, Archiv, B 12/31.

ferred to the beginning of the cremations, the figure for the number of cartloads shown next to it would concern the amount loaded into the gasifiers, which cannot be the case.

Moreover, this hypothesis would lead to technical impossibilities, as we can gather from the explanatory table (Document 256). In this table, Column 1 indicates the date of the various cremation cycles, Column 2 the total consumption of coke, Column 3 the total number of cremations, Column 4 the average coke consumption for each cremation, Column 5 the total time for each cycle (based on the first column of the list of cremations), Column 6 the average duration of each cremation (provided the first and last figures of the list refer to the beginning and the end of the cremations), and Column 7 gives the hearth grate's throughput rate under the same conditions.

We see immediately that the duration of the cremations (Column 6) in certain cases would be only 13, 12 or even 8 minutes, but if we follow Kessler's experiments, these times would not even be sufficient for the complete evaporation of the corpse water.

Next, the average duration of discontinuous cremations (26 September – 15 December) – 17 minutes – would be less than the duration of cremations run continuously (31 October – 12 November) – 23 minutes – whereas the contrary should be the case.

Finally, for this hypothesis the coke consumption for each hearth would be 163 kg/hr for the cremations between 26 September and 15 October (Column 7) and 80 kg/hr for those between 31 October and 12 November.

According to the Colombo Engineering Handbook, the throughput of a hearth grate under natural draft is about 90 to 120 kg of coal per hour per square meter (Colombo 1926, p. 398). For the Topf Furnaces, the maximum figure applies, as we can gather from the file memo (*Aktenvermerk*) of 17 March 1943,[499] which gives the grate throughput for the triple- and 8-muffle furnaces: 35 kg of coke per hour.

As the surface area of the hearth grates for the triple-muffle furnaces was 0.3 m² (cf. Subchapter 7.2.), the unit throughput on 1 m² was (35÷0.3=) 116.7 kg or about 120 kg per hour.

As far as forced draft is concerned, the following data are found in Colombo's engineering handbook (Colombo, p. 366; in the third column the data for the furnace of the Gusen Camp is shown):

Draft [mm water column]	Throughput [kg/(hr×m²)]	Gusen Furnace (one hearth) Throughput [kg/hr]
10 – 20	120 – 150	30.0 – 37.5
20 – 30	150 – 180	37.5 – 45.0
That is to say:		
10	120	30.0
20	150	37.5
30	180	45.0

[499] APMO, BW 30/7/34, p. 54; cf. Subchapter 10.8. and Document 264.

According to Heepke, chimneys of the cremation furnaces operated with a maximum draft of 30 mm of water column (Heepke 1905b, p. 71). Even the three draft enhancers initially installed at Crematorium II of Birkenau operated with a draft of 30 mm of water column for a flow rate of 40,000 m³/hr of flue gas and a 380-V motor of 15 hp each (see invoice quoted on p. 269).

The forced-draft device for the Gusen Furnace was a standard device, also installed at the Auschwitz Crematorium, with a throughput of 4,000 m³/hr and a 3-hp engine. The working pressure is not known, but could not have been more than 30 mm of water column in any case.

Looking at the summary (Document 256), it is obvious that a daily average throughput of 163 kg/hr of coke on each grate – even a lower one of 78 kg/hr for November 1941 – would have been technically impossible, because even at maximum draft of 30 mm water column, the Gusen Furnace could only have handled 45 kg/hr of coke each.

The only conclusion we can draw from the above considerations is that the individual entries for the coke supply refer *neither* to the coke loaded into the gasifiers *nor* to the amount consumed up to the time mentioned in the lists, but to the coke brought from time to time to the gasifiers from the coke storage area of the crematorium so that the attendants would always have a sufficient amount of coke available.

As in any change of shifts, the attendant took over the unloaded coke and was responsible for its use, indicating the time and the number of cartloads when the unloading ended, not when it began. The furnace, though, would be operated as soon as the first load had arrived. Hence the indication “time” on the document in question does not by itself refer to the beginning of the cremation but to the end of the delivery of the first batch of cartloads.

This, again, means that the times recorded in the first column of the list correspond neither to the beginnings nor to the ends of the cremations, which therefore began before the first hour entered and ended later than the last.

As far as the average coke consumption is concerned, it is likely that a certain amount of coke was left over after the end of a cremation cycle and was used for the beginning of the following series of cremations, but it is just as likely that this amount was always more or less the same (an amount necessary for restarting the furnace) in such a way that, overall, what remained at the end of the day was used for the start-up of the furnace for a new cycle of cremations.

Here, however, we run into the fundamental problem: how can we determine the times of the beginnings and the ends of the cremations?

To solve this problem, one can use the duration of the combustion of coke in the gasifier hearths. First, though, we must determine the total time over which the 677 cremations were carried out. If we assume that they began at 7:00 AM on 31 October and ended at 11:00 PM on 12 November (i.e. 12 ⅔ days), we have a total time of 304 hours or 18,240 minutes. The time needed for the combustion of 20,700 kg of coke actually consumed obviously depends on the throughput rate of the gasifier grates; as the time taken for the consumption of

the coke is inversely proportional to the throughput rate of the grate, with the shortest time corresponding to the highest throughput rate.

We have seen that the highest throughput rate for the two hearths obtainable with a forced draft of 30 mm of water column was about (2×45=) 90 kg/hr of coke overall and we thus find:

– total combustion time of the coke: 20,700 kg ÷ 90 kg/hr = 230 hours or 13,800 minutes
– average daily activity of the furnace: 230 hrs ÷ 12.67 days ≈ 18 hr/day
– average time of coke combustion for each corpse (30.6 kg/corpse ÷ 45 kg/hr) × 60 min/hr ≈ 41 minutes
– average daily shut-down time of the furnace: ≈ 6 hours
– heat loss from the furnace during shut-down: ≈ 200,000 kcal[500]
– time spent daily on reheating the furnace to operating temperature (with an efficiency of $\eta \approx 0.54$):[501]

$$\frac{200{,}000\ \text{kcal} \cdot 60\ \text{min/hr}}{90\ \text{kg/hr} \cdot 6{,}470\ \text{kcal/kg} \cdot 0.54} \approx 40\ \text{minutes;} \qquad [109]$$

– daily coke consumption for preheating the furnace to operating temperature: 90 kg/hr × (40 min ÷ 60 min/hr) = 60 kg of coke;
– total preheating time of the furnace: 40 min/day × 12.67 days ≈ 510 minutes;
– total amount of coke used for reheating the furnace: 60 kg/day × 12.67 days ≈ 760 kg;
– average duration of the cremation of a corpse: (13,800 min – 510 min) ÷ 677 corpses × 2 muffles ≈ 40 minutes/corpse
– daily operating time of the furnace: about 18 hours, of which about 17 hr 20 min for cremations and about 40 min for preheating
– average coke consumption for each cremation: ≈ 30.6 kg, of which (20,700 kg – 760 kg) ÷ 677 ≈ 29.5 kg for the corpse and 1.1 kg for preheating the furnace.

These data represent *minimum theoretical* values; if, in fact, a grate throughput rate halfway between the maximum (90 kg/hr) and the minimum (20,700 kg ÷ 304 hrs = 68 kg/hr) is assumed, *i.e.* ca. 80 kg/hr, we obtain the equivalent of an average daily operating time of the furnace of about 20 hours, and the average duration of a cremation would be 45 minutes, while the average amount of coke for preheating the furnace would drop to 0.8 kg for each cremation.

As the heat balance as calculated in Chapter 10 will be based on minimum theoretical values corresponding to an average daily operating time of 18 hours, the amount of coke would go down negligibly for an operating time of 20 hours per day: (1.1 – 0.8 =) 0.3 kg per cremation, *i.e.* by about (0.3÷30.6=) about 1 percent.

According to the Topf operating instructions for the double- and triple-muffle furnaces, the post-combustion of the corpse residues took about 20 minutes; adding to this the time needed for the main combustion – 40 minutes – one ob-

[500] Calculated on the basis of a heat loss of 41,709 kcal during the operation; cf. Subchapter 10.2.
[501] The calculation is explained in Subchapter 10.3.

tains for the total duration of the cremation process a time of 60 minutes, which represents the limit called "thermal barrier" by Dr. Jones, *i.e.* the minimum duration which cannot be pushed any lower (cf. Unit I, Chapter 6) by any practical means.

This duration is valid for the furnace of the Gusen Camp and, as I shall explain in Subchapter 8.5., cannot be applied directly to the inferior Auschwitz double-muffle furnace, to which the Topf letter of 14 July 1941 refers explicitly.

8.4. The List of Cremations at the Westerbork Crematorium

The crematorium of the Westerbork Camp in the Netherlands was equipped with a coke-fired Kori Furnace. The "operating instructions for cremations" which exist in the camp documentation refer to the oil-fired Kori Furnace (cf. Document 286) and make sense only if the furnace worked initially with this fuel.

The furnace was, without doubt, a mobile oil-fired furnace that was later converted into a coke-fired furnace by the addition of a gasifier, probably as shown on the Kori Drawing J. Nr. 9239 of 15 February 1944.[502] The crematorium went into operation on 15 March 1943 at a time when the mortality was still very low but rising sharply. In 1943, the number of deaths rose to 593 from 108 in the second half of 1942 and then went down drastically: to 50 in 1944 and 4 in 1945.[503] A number of documents concerning this crematorium have survived. The most-important ones are:

– a large fragment of the "*Krematorium Betriebsbuch*" indicating the names of the persons deceased between 23 June 1943 and 31 March 1944, with dates of birth and death and consecutive registration numbers (277 to 510) corresponding to the number on the urn used;[504]
– numerous cremation lists giving the number of corpses cremated, the duration of each cremation, and the total coke consumption (cf. Documents 257f.).

There is also a "name list of Jewish persons who died in the concentration camps of Westerbork and Buchenwald and were buried in Dutch cemeteries," drawn up by the Dutch Red Cross, giving an alphabetical list of the Jews who died at Westerbork, complete with their dates of birth, of death and of cremation, as well as the urn number.[505]

As the cremations were carried out in the order of the entries, these documents allow us to personalize the cremation lists by linking each number with the corresponding name list. For the first three months, the lists have many gaps. Hence we can only identify the day of a cremation and the number of cremations carried out. The day with the highest activity, of 17 cremations, was

---

[502] H. Kori, drawing J.Nr. 9239 "*Anbau einer Kohlenfeuerung am ölbeheizten Krematoriumsofen*" dated 15 February 1944. ÖDMM, Archiv, N 17, Nr. 6.
[503] *Rapport over de sterfte in het Kamp Westerbork in het tijdvak van 15 Juli 1942 tot 12 April 1945* (Report on the mortality at camp Westerbork over the period from 15 July 1942 through 12 April 1945). ROD, C[64] 514, p. 1
[504] ROD, C[64] 292.
[505] ROD, C[64] 314.

14 May 1943. The first list we have covers 27 April 1943, followed by the list for 10 May after a gap of four operating days.[506]

The lists of individual cremations are listed in the Appendix, although without the names. I have omitted the small number of lists for 1943 in which there are only five cremations or fewer (with one exception to be explained later) and those for 1944, a year with very few cremations. The list shows:

– the number of cremations
– the consecutive registration numbers
– the sex of the deceased
– the age of the deceased
– the date of birth of the deceased
– the date of death of the deceased
– the beginning and the end times of the cremation
– the duration of the cremation.

In order to allow the proper interpretation of the data presented, we must give some further explanations.

Cremations were not carried out every day, but only when a sufficient number of corpses had been collected in the morgue. This was done to save fuel.

In the Westerbork Camp, there was a very high infant mortality, with peaks of 25% in May and June of 1943, and even 40% in August.[507] It concerned for the most part babies who were a few months and at times only a few days old, and who were normally cremated by placing two small corpses into the muffle, or at times one infant and an adult corpse.

A few small corpses were introduced between two consecutive cremations of adults in such a way that their cremation overlapped the final phase of the preceding corpse and the initial phase of the following corpse.

In the cases of double cremations, entries concerning the corpse of the infant are marked with an ×. In Document 258, this is the case for the seventh and the eighth cremations (a 90-year-old woman and a baby girl two months of age) and for the eleventh and twelfth cremations (a 46-year-old man cremated together with a child of ten months).

Even though the cremations generally followed strictly the consecutive order of the morgue entries, there are some gross anomalies which lead us to believe that the order was mixed up in these cases. For example, the seventh cremation on 26 May 1943 lasting 25 minutes cannot possibly have referred to a man of 72, but obviously concerned a child of two months listed as No. 9. Similarly, the third and the fifth cremations on 4 June must have been swapped, as it is difficult to see how the cremation of a 78-year-old woman should have taken 35 minutes, whereas that of an 18-month-old child extended over one whole hour. A similar switch must also be assumed for the fourth and fifth cremations on 11 June where the cremation of the corpse of a one-year-old child is said to have taken an unlikely 55 minutes, and that of an 81-year-old man only 35 minutes.

---

[506] Although there are 13 days between 27 Apr. & 10 May, the crematory operated only on four of these days.

[507] Rapport… *op. cit*. (note 503), p. 2.

Also, the first and third cremations on 18 October 1943 (lasting 20 minutes), referring respectively to a man of 45 and a woman of 59, must obviously take the place of the second and fourth cremations attributed to a child aged one month and another child aged two months.

After these cases have been corrected accordingly, we can interpret the tables in the Appendix in a valid manner.

8.4.1. Adults Cremated Individually

There are altogether 128 individually cremated adults. In the table below I have listed the number of corpses cremated in the order of the duration of the cremations. The average duration of one of these 128 cremations was 50 minutes:

Duration [min]	# of corpses	Duration [min]	# of corpses
30	6	65	3
35	5	70	2
40	19	75	2
45	24	80	3
50	21	90	2
55	15	95	1
60	25	*Total:*	128

8.4.2. Infants Cremated Individually

As explained above, children's corpses were, as a rule, cremated together with another child or an adult. There are only seven individual cremations of children, as listed in the table below, together with the respective ages of the infants:

Duration [min]	# of corpses	Ages
20	2	2 months 1 day
30	1	5 months
35	2	18 months 12 months
40	2	1 month 2 months
Total:	*7*	

8.4.3. Infant Double Cremations

The lists mention seven cremations of this type, four of which, however, are obviously abnormal. Let us first consider the regular cases:

Duration [min]	# of corpses	Ages
20	2	2 months 1 day
30	3	1 month 5 months 3 months
40	2	3 years 2 years

The other four cases show obviously abnormal data:

Duration [min]	# of corpses	Ages
45	2	8 months 10 months
50	2	2 months 1 day
70	2	17 months 4 years
75	2	8 months 14 months

When comparing these entries with those in the table above, one can see that these cremations should have taken 20 or 30 minutes. Nothing justifies such long durations, unless we assume errors in the entries of the dates of birth or that each pair of corpses consisted of one adult and one child. The latter hypothesis seems to be the most-reasonable explanation, which we will therefore adopt in this case.

8.4.4. Mixed Double Cremations

There are 56 corpses to be considered here, or 28 pairs. The average age of the adults was 70 years, that of the children about 1 year:

Duration [min]	# of corpses	# of cremations	Total min
40	2	1	40
45	16	8	360
50	8	4	200
55	4	2	110
60	14	7	420
70	4	2	140
75	4	2	150
80	2	1	80
105	2	1	105
Totals:	*56*	*28*	*1605*
Average:	*1605 min ÷ 28 = 57.32 min*		

8.4.5. Staggered Cremations

There are four instances of cremations in the course of which an additional corpse was introduced before the cremation of the preceding one had ended. We shall consider the cases one-by-one.

a) 10 May 1943

Cremation order	Time	# of corpses	Age
Second	09:15 – 10:10	1	65 years
Third	09:50 – 10:30	1	27 months
Fourth	10:10 – 11:00	1	69 years

The corpse of a child 27 months old was introduced into the furnace 35 minutes after the introduction of the corpse of a 65-year-old man; the child's cremation lasted 40 minutes and overlapped the cremation of the latter corpse for the first 20 minutes; for the remaining 20 minutes, it overlapped the cremation of the corpse of a 69-year-old woman, introduced at 10:10 AM.

b) 26 May 1943

Cremation order	Time	# of corpses	Age
Seventh	13:15 – 13:40	1	2 months
Eighth	13:30 – 15:30	1	4 years
Ninth	13:30 – 15:30	1	72 years

The cremation of the corpse of a child of two months took 25 minutes; ten minutes before it ended, two corpses were introduced simultaneously into the furnace, the corpse of a woman aged 72 and that of a child of four years of age. The cremations took two hours altogether.

c) 1st September 1943

Cremation order	Time	# of corpses	Age
Fourth	10:40 – 11:35	1	50 years
Fifth	11:00 – 11:35	1	1 day

At 10:40 AM, the body of a 50-year-old woman was introduced into the furnace; 20 minutes later, the corpse of a baby who had died at birth was added. Both cremations were over by 11:35, the cremation of the woman lasted 55 minutes, that of the baby 35 minutes.

d) 22 June 1943

Cremation order	Time	# of corpses	Age
Third	10:20 – 11:20	1	81 years
Fourth	10:20 – 10:50	1	14 months
Fifth	10:55 – 11:35	1	84 years

At 10:20 AM, the corpse of an 81-year-old woman was introduced into the furnace, together with the body of a girl aged 14 months; 35 minutes later, another corpse was added, the cremation of which ended at 11:35 AM. Hence the bodies of two adults and one infant were cremated within 75 minutes. This would be an exceptional case for two reasons, both on account of the short overall duration of the cremation, and because in the available documents no other case involving the concurrent or staggered cremation of two adults can be found.

If we are not dealing with a mistake in the log entries, this would be a most-unusual event; on both accounts, we may discard this case.

The *only* case of a concurrent cremation of two adult corpses *apparently* took place on 1st July 1943, the day on which the eighth and ninth corpses were introduced into the furnace at the same time, *i.e.* 1:30 PM; according to the *Betriebsbuch* of the crematorium, the cremation concerned a man of 73 and a young man of 20. However, in the cremation list for that day, the ninth corpse is marked with an × and was therefore the corpse of a child. This is borne out by the fact that the other two corpses marked in the same manner – the fifth and the eleventh – do concern the corpses of a one-year-old child and that of a child 20 months old. This suggests that the second body was not a 20-year-old male, but a 20-month-old boy.

In the Westerbork Crematorium, the end of the cremation corresponded to the moment when the corpse residues went into the ash compartment, and the muffle was thus ready for a fresh corpse. As we have seen, the average duration of cremations involving individual adults was 50 minutes. This confirms basically the value derived from Kessler's experiments, except for the fact that Kessler's value referred to the average duration of the cremation process up to the maximum point of the main cremation; hence, the average value for the Westerbork cremations is a little lower. This difference may have been caused by various factors, such as the modal type of corpse or the structure of the muffle grate.

The 600 cremations carried out in the crematorium of the Père-Lachaise Cemetery in Paris between 1889 and 1893 (cf. tables pp. 100f.) provide us with the following data: The cremation of a child nine years old or less took some 39 minutes on average, cremations of children ten and over and of adults took some 61 minutes.

8.5. Conclusions

From an analysis of the data given above, we may draw the following conclusions:

1. The *minimum* duration of the main combustion of a corpse introduced without coffin into the muffle is approximately half an hour under optimum conditions, *i.e.* when the cremation chamber is constantly maintained at a temperature of at least 850°C; at lower temperatures, the process takes longer.
2. The *minimum* duration of the cremations carried out in the Gusen Furnace over the period mentioned was 40 minutes on average with the furnace in

thermal balance[508] and in continuous operation. This duration is valid for the Gusen Furnace. It cannot be applied directly to the Auschwitz double-muffle furnace, to which the Topf letter of 14 July 1941 refers explicitly. In support of this, we may cite the following facts:

– The Gusen Furnace had a refractory grate of three transverse bars, placed about 30 cm from each other, as well as a longitudinal bar in the center; thus, the plane of the grate had eight openings some 30 cm × 25 cm in size, whereas the grate of the Auschwitz furnaces consisted of five transverse bars (*Schamotte-Roststeine*) placed 20 cm from each other (or even of bars with an opening of hardly 5 cm). This means that the grate of the Gusen Furnace allowed larger corpse remnants to drop into the ash chamber. Hence the muffle emptied itself more rapidly, with the main combustion finishing not in the muffle but in the ash chamber below.
– Although the Auschwitz crematorium possessed a forced-draft system of the same type as the Gusen Furnace, the latter served only two muffles, whereas the Auschwitz device served six. Hence, when all the three furnaces were in operation, each one was allotted only a third of the draft available for a single furnace. Therefore, under forced-draft conditions, the Auschwitz Furnaces could not attain the performance of the Gusen Furnace. In the summer of 1942, this draft enhancer was even completely removed at Auschwitz when the chimney of the crematorium was rebuilt (cf. Subchapter 6.1.).

3. The duration of the cremations at Westerbork was 50 minutes, which is in rough agreement with Kessler's experiments.
4. On account of the greater amount of heat available in the Kori Furnace at Westerbork with its hearth grate of 0.8 m × 0.6 m and a coke throughput rate of some 58 kg/hr[509] – as compared to the hearth grate of 0.5 m × 0.5 m and a coke throughput of some 30 kg/hr for the Auschwitz double-muffle furnaces – and also taking into consideration the Topf letter of 1st November 1940 mentioned above, one may assume an average duration of one hour for cremations of normal corpses in the Topf Furnaces at Auschwitz-Birkenau.

This duration – which includes the time needed for the introduction of a corpse into the muffle, some three minutes (cf. Subchapter 9.3. below), and the time for cleaning the muffle after the cremation[510] – was confirmed by two Topf engineers during their interrogation by the Soviet counter-espionage service (SMERSH). On 5 March 1946, the Soviet interrogator Shatanovski asked Prüfer:[511]

> *"How many corpses could be cremated at Auschwitz in one crematorium in one hour?"*

The Topf engineer replied:

---

[508] Thermal balance is the state of the furnace where the furnace brickwork no longer absorbs any additional heat to reach the operating temperature.
[509] H. Kori Drawing J.Nr. 9239.
[510] This procedure is mentioned by Fritz Sander in his letter of 14 September 1942; cf. Section 7.4.1.
[511] Interrogation of K. Prüfer on 5 March 1946. FSBRF, N-19262, pp. 33f.

> *"In a crematorium of five furnaces or fifteen openings* [muffles] *fifteen corpses were cremated in one hour."*

This amounts to the cremation of one corpse in one muffle in one hour. The previous day, the Topf engineer Karl Schultze, who was thoroughly familiar with the triple-muffle furnaces because he had designed their blowers, had stated:[512]

> *"In each of two crematoria there were five furnaces and three corpses were introduced from time to time into each furnace, i.e. there were three openings* [muffles] *in one furnace. In one hour, fifteen corpses could be burned in a crematorium with five furnaces."*

Hence, Schultze as well confirmed a cremation throughput rate of one corpse per muffle in one hour.

We still have to explain why the Topf letter of 14 July 1941 speaks of a duration of 33 to 40 minutes per cremation. The answer lies in the forced draft for the furnace obtained by means of the forced-draft device (*Saugzuganlage*). That the duration of a cremation can actually be reduced in this manner is supported by experiments carried out in 1939 with a Topf Furnace, albeit a gas-heated model, in the Gera Crematorium. The engineer Heinrich Stenger says in this respect (Stenger 1939, pp. 17f.):

> *"In the course of one shift, up to 8 incinerations are carried out. If needed, the incineration times may be shortened by switching on a suction device, thus allowing more than 8 incinerations. It has yet to be ascertained, however, whether it is more-advantageous to accept longer incineration times in order to maintain the service life of the furnace rather than reduce the service life by raising its throughput by means a suction device."*

In coke-fired furnaces the effect of a forced draft was even greater.[513]

The data given in the Topf letter of 14 July 1941 were probably based on the practical experiences with the Gusen Furnace, rather than the furnaces at Auschwitz, and the maximum capacity of 30 corpses in 10 hours (or 40 minutes per cremation) can be considered to be the maximum capacity obtainable under forced-draft operation; the capacity of 36 corpses in 10 hours (or 33 minutes per cremation) may represent the theoretical limit of the installation, attainable only for a short period of time and under optimum conditions.

Taking into account that the cremations of children under 9 in the Père-Lachaise Crematorium took 39 minutes on average, we may also be dealing with somewhat-inflated figures as a sales pitch.

As far as the Central Construction Office letter of 28 June 1943 is concerned (Document 248) and Prüfer's memo of 8 September 1942 (Document 249), we see right away that the cremation capacity mentioned for individual cremations is technically impossible. When we look at Prüfer's memo of 8 September 1942, we must remember that at that time the furnaces with three and eight muffles had not yet been built at Auschwitz, and that the figures stated for the cremation capacities were not based on experience but rather on mere expectations.

---

[512] Interrogation of K. Schultze on 4 March 1946. FSBRF, N-19262, p. 52.
[513] Cf. Unit I, Section 2.2.4.

It is true that the first triple-muffle furnace had already been completed at *KL* Buchenwald on 23 August 1942, but between 23 August and 8 September the average mortality there amounted only to some 10 deaths per day.[514] Therefore the cremation capacity of (800÷5 furnaces=) 160 corpses per day in a triple-muffle furnace could in any case not be based on operational results achieved with the furnace but was simply an extrapolation. Furthermore, the memo in question presents inexplicable contradictions with other documents as well as with the facts.

One such contradiction is the fact that the cremation capacities of the individual plants listed in the memo are in extreme and random disagreement with those given in the third document mentioned above, *i.e.* the Central Construction Office letter of 28 June 1943. In the last document, as we have seen, the six muffles of Crematorium I are listed with a daily capacity of 340 corpses, the five triple-muffle furnaces at Crematoria II and III with 1,440 corpses, and the 8-muffle furnaces at Crematoria IV and V with 768 corpses per day.

Prüfer's memo instead gives the six muffles of Crematorium I a daily capacity of 250 corpses (73.5% of the above figure), the five triple-muffle furnaces at Crematoria II and III one of 800 corpses (55.5%) and the eight muffles of Crematoria IV and V a capacity of likewise 800 corpses (104.1%).

Prüfer's memo contains yet another, even more-mysterious contradiction: it attributes to the eight muffles of the future Crematoria IV and V the same capacity of 800 corpses per day as to the 15 muffles of the future Crematorium II. It follows that the 8-muffle furnace would have had a cremation capacity per muffle almost twice that of the five triple-muffle furnaces: (800÷8=) 100 corpses per muffle and day against (800÷15=) 53. This is completely out of line with reality, because by its very design the 8-muffle furnace had an even lower efficiency than the triple-muffle furnace (cf. Mattogno 2019, Subchapter 12.3., pp. 398-402, for a more details).

We have yet to deal with the question whether and within what limits the Topf Furnaces at Auschwitz-Birkenau allowed multiple cremations (for example, of four corpses in one muffle within 60 minutes), in which case the capacities given in the letter would have a foundation in reality. This problem will be analyzed in the next chapter.

9. The Cremation Capacity of the Cremation Furnaces at Auschwitz-Birkenau

The duration of the cremation process is an important factor for judging the capacity of such installations, but it is not the only one. There are two more factors which matter in this case: the duration of the "duty cycle" of the furnace as well as its load. It is easy to see that the overall cremation capacity rises with

[514] At Buchenwald, 335 detainees died between 3 and 30 August, and 203 detainees between 31 August and 27 September; Internationales Lagerkomitee Buchenwald 1949, p. 85.

the length of time the furnace operates over the span of a day and with the number of corpses loaded into each muffle.

In this chapter we will deal primarily with these technical problems and determine the maximum theoretical capacity of the furnaces at Auschwitz-Birkenau. Such an analysis would, however, be incomplete without a simultaneous treatment of the question regarding the normal cremation capacity of these furnaces, which may be summarized by the following question: What was the capacity for which the Birkenau Furnaces were *designed*?[515] This is a historical question which concerns the genesis, the function, and the purpose of the crematoria at Birkenau.

9.1. Continuous Operation of the Furnaces

In line with all solid-fuel (and fixed-grate) combustion plants, the operation of coke-fired cremation furnaces depended on the capacity of the hearth grate which inevitably decreases with time (since last cleaning) because of the formation of slag. For this reason, the Topf instructions for the operation of double- and triple-muffle furnaces specify (cf. Documents 210 & 227):

> *"Each night, the gasifier grate must be freed from the coke slag and the ash must be removed."*

Let us take a closer look at the problem.

9.1.1. The Formation of Slag

In a contemporary technical article on the subject of (boiler) grates, it is stated (Schulze-Manitius 1935, p. 89):

> *"Any fuel, even washed coal, carries incombustible substances along into the hearth, which will liquefy if the temperature is high enough, flow through the fuel layers and solidify again underneath the grate under the effect of the cooling provoked by the combustion air. This slag must be removed because it obstructs the feed of combustion air."*

The formation of slag in gasifier hearths was an inevitable phenomenon, because the melting temperature of the slag, while varying between 1000 and 1500°C depending on the type of coal, is usually 1,100 to 1,200°C (ter Linden 1935, p. 14), whereas the hearth temperature is around 1,500°C (H. Keller 1928, p. 3). The slag from the fossil coal of Upper Silesia used at Auschwitz had a melting temperature of 1,200 to 1,300°C (see Subchapter 9.7.).

In order to gain an appreciation of the amount of slag forming on the grates, one may refer to Kessler's experiments of 5 January 1927 which, for a load of 436 kg of coke, yielded some 21 kg of (4.8 %) of "incombustible" material in the form of slag. If we apply this percentage to the Topf triple-muffle furnace, the same amount of slag would have been produced in each of the two gasifiers over an operation of 18 hours with normal corpses.

---

[515] This question does not arise for the history of Crematorium I at Auschwitz.

9.1.2. Slag Removal

The slag was removed from the grate's surface by means of two tools: a poker, or straight rod, for breaking off the slag, and a scraper for pulling out the slag fragments (cf. Document 259 and Photos 366f.). This method of cleaning obviously required that the grate was clear (and the gasifier hence not in operation), because the work was carried out from both above and below.

The grates of the triple-muffle furnaces consisted of twelve square steel bars (*Vierkanteisen*) measuring 40 mm × 40 mm × 630 mm, and of two transverse supporting bars (*Auflager-Eisen*) 40 mm × 40 mm × 740 mm. As the bars were imbedded in the brick walls of the gasifiers, the grate dimensions were 600 mm × 500 mm. The steel bars were arranged in such a way as to form a central slot some 20 mm wide and ten lateral slots some 10 mm wide each. In front of the the grate, in the upper part of the hearth door, the brickwork had an arched shape, the center of which was about 10 cm above the grate (cf. Photos 167, 174 and 177).

The hearth doors (*Feuertüren*) were set at floor level; the grate was some 20 cm above floor level. Once the fire on the hearth had gone out, the attendant opened the ash-chamber door, removed any embers with the scraper, broke off the layer of slag with the poker, possibly using a curved rod to free the slots from beneath, and scraped out the residues with the scraper.

The down-time depended not only on the duration of the cleaning operation as such, but also on the time needed for cooling the furnace down and restarting it later.

According to the letter of 23 October 1941 written by Hans Kori to *SS Sturmbannführer* Lenzer at *KGL* Lublin, the production of hot water – heated by means of the exhaust gas from the five-muffle furnace Kori had built for the crematorium – for 50 showers in continuous operation was based on a daily operating time of 20 hours.[516] As Kori in this case was aiming for maximum production, it is clear that he was taking a daily down-time of four hours for the furnaces into consideration, and this down-time could have no reason other than for cleaning the grates. We may thus assume that the continuous operating period of the furnaces was 20 hours per day under normal conditions.

This obviously does not mean that the furnaces could not operate continuously for a longer span of time than 20 hours, but that 20 hours was a duration which ensured their optimum performance; beyond this value, the efficiency of the grates gradually diminished, and eventually operation would cease altogether. Greater amounts of slag would have caused considerable difficulties and longer down-times for their removal. The best way of running the furnaces was therefore to operate them continuously but with a daily interval for cleaning the grates.

[516] APMM, sygn. VI-9a, Vol. 1.

9.2. Concurrent Cremation of Several Corpses

For an assessment of the performance of the Topf Furnaces, we must examine whether, and if so to what extent, it would have been possible to raise the cremation capacity by increasing the load by introducing two or more corpses at once into one muffle.

In crematoria for civilian use this was prohibited by law; at the crematorium of the Westerbork Camp, it was done only in a limited number of cases by placing the corpse of a small child next to an adult corpse. At the crematorium of the Terezín Ghetto with its four oil-fired furnaces (see Subchapter 11.4.), the simultaneous presence of two corpses in one muffle was normal, but they were and processed in a staggered manner. Such a procedure required a furnace design totally different from that of the Topf Furnaces installed in concentration camps. The performance of the Terezín Crematorium therefore cannot be used as a reference point for the problem we are considering here. This question will be discussed at greater length in Chapters 11.5f.

9.2.1. Experiments with Animal-Carcass-Incineration Furnaces

From a merely technical point of view, what comes closest to the concurrent combustion of several corpses in one muffle is the operation of furnaces for the destruction of animal carcasses. Although such a comparison might appear disrespectful,[517] data collected with such furnaces provide reliable reference points for the cremation of corpses as well – from a purely technical point of view.

Document 260 provides us with the operational results for eight carcass-destruction furnaces built by the Kori Co. as already described in Chapter 10 of Unit I. On the basis of this document, I have established the data given in Table 4 below.

Table 4: Features of Animal-Carcass-Incineration Furnaces

Type	Load	Coal used	Cremation Time	$\frac{\text{kg Coal}}{\text{kg Load}}$	$\frac{\text{Time}}{\text{kg Load}}$	$\frac{\text{kg Load}}{\text{min}}$
1a	250 kg	110 kg	5 hr	0.440	72 sec	0.83
1b	310 kg	130 kg	6 hr	0.419	70 sec	0.86
2a	370 kg	150 kg	7 hr	0.405	68 sec	0.88
2b	450 kg	170 kg	8 hr	0.377	64 sec	0.94
3a	540 kg	200 kg	9.5 hr	0.370	63 sec	0.95
3b	650 kg	225 kg	10.5 hr	0.346	58 sec	1.03
4a	750 kg	265 kg	12 hr	0.353	58 sec	1.04
4b	900 kg	300 kg	13.5 hr	0.333	54 sec	1.11

[517] Although what happens in real life is at times even more-disrespectful. For example, the city of Genoa has been authorized to send to the municipal refuse incineration station the residues of exhumations and of remains from mausolea at the Staglione Cemetery with the instruction that the "operation of the plant must be carried out in keeping with the legal norms for the elimination of refuse." *Bollettino…* 1992. Regulation No. 22, Item f, of the Italian Region of Liguria, decreed on 22 February 1997, defines as solid urban refuse "refuse stemming from exhumations and remains from mausolea, as well as other refuse stemming from cemetery activity […]." Regione Liguria 1998.

The preheating of the furnace up to thermal balance (steady state) requires both time and fuel, and may be calculated in the following way (for Furnace Type 1a):

– Mass of the brickwork: 950 kg
– Hourly coke feed: 110÷5 = 22 kg
– Hearth efficiency (acc. to Heepke): 0.75
– Lower heating value of hard coal: 7,500 kcal/kg
– Coal required for heating the brickwork from 20°C to 800°C:

$$\frac{950\ \text{kg} \cdot 0.21\ \text{kcal kg}^{-1}\ \text{°C}^{-1} \cdot (800\text{°C} - 20\text{°C})}{7{,}500\ \text{kcal kg}^{-1} \cdot 0.75} \approx 28\ \text{kg} \qquad [110]$$

– Hard-coal consumption other than for preheating of furnace: (110 – 28) = 82, or (82 ÷ 250 =) 0.328 kg for 1 kg of organic substance.
– Assuming that the first 28 kg of coal were used to preheat the furnace without any cremations taking place, this results in a maximum preheating time of (28 kg ÷ 22 kg/hr) ≈ 1.27 hr, yielding a minimum net cremation time of (5 – 1.27) some 3.73 hours, which in turn yields a maximum cremation rate of (250 kg ÷ 3.73 hr ÷ 60 min/hr) ≈ 1.12 kg/min.

Applying this method to the other furnace models as well, we obtain the following data, where the last column gives the surface area of the combustion chamber:

Table 5: Corrected Features of Animal-Carcass-Incineration Furnaces

Type	Load	Coal used	Cremation time	$\frac{\text{kg Coal}}{\text{kg Load}}$	$\frac{\text{kg Load}}{\text{min}}$	Chamber Size
1a	250 kg	110 kg	5 hr	0.328	1.12	0.68 m²
1b	310 kg	130 kg	6 hr	0.325	1.12	0.90 m²
2a	370 kg	150 kg	7 hr	0.310	1.15	1.11 m²
2b	450 kg	170 kg	8 hr	0.295	1.20	1.38 m²
3a	540 kg	200 kg	9.5 hr	0.290	1.22	1.65 m²
3b	650 kg	225 kg	10.5 hr	0.275	1.30	1.97 m²
4a	750 kg	265 kg	12 hr	0.280	1.31	2.29 m²
4b	900 kg	300 kg	13.5 hr	0.268	1.39	2.67 m²

These data are useful as reference points for the subject of this section as well, because they deal with practical cases were several carcasses or parts thereof were incinerated in the same combustion chamber.

Furnace Model 2b had a combustion chamber with a floor area of 1.38 m², practically equal to that of a muffle of Topf's triple-muffle furnace (1.4 m²); in this device, the cremation of several corpses of a total weight equal to the maximum load (450 kg or 326 kg/m²) proceeded at a rate of 1 kg in 50 sec. If we apply this rate to a corpse of 70 kg, we obtain (70 kg × 50 sec/kg ÷ 60 sec/min) ≈ 58 minutes, which is more-or-less the same time as for an individual cremation in the Topf Furnace (60 minutes).

In the furnace with the highest throughput, Model 4b, the cremation of a corpse of 70 kg would have required (70 kg × 43 sec/kg ÷ 60 sec/min=) 50 minutes.

We may thus conclude that exceeding the thermal design limits of the Topf furnaces by overloading the muffles would not have led to any gain in productivity. Quite to the contrary: the maximum cremation capacity of the Topf Furnaces are based on the introduction of a *single* normal corpse into the muffle, in line with the design parameters.

9.2.2. Experiences with the Westerbork and Gusen Crematoria

The practical experience gathered for cremations carried out at Westerbork and Gusen fully bears out the above conclusion.

As we have seen, cremations of two adult corpses together were never undertaken at the Westerbork Crematorium, except in one rather-dubious case, which carries no weight on account of its conditions. The only kind of double cremations at that location involved the concurrent incineration of one adult corpse grouped with the corpse of a small child, and it is clear that these cremations which go against of the ethics and esthetics of civilian crematoria were motivated only by reasons of thermo-technical economy.

But then, if it had been thermo-technically economical to cremate two or more adult corpses simultaneously, why did the attendants of the crematorium never proceed that way? The answer is contained in the fact that during occasional cremations of one small child together with one adult corpse it had been observed that the small corpses had a significant effect on the cremation process, extending its average duration by 14% (from 50 to 57 minutes) beyond the average cremation time of single adult corpses. This effect shows in its tendency that two normal adult corpses loaded concurrently would basically have doubled the duration of the cremation.

This is in agreement with the cremations carried out in the crematorium of the Père-Lachaise Cemetery mentioned earlier. In fact, the time needed for the cremation of children under nine years of age was around 39 minutes, whereas it took some 61 minutes to cremate children or adolescents aged ten or over – a rise of 56%. Thus, the concurrent cremation of several corpses in one muffle would have tended to lengthen the time needed in proportion to their weight.

As far as the Gusen Furnace is concerned, we possess, for the period of its continuous operation (30 October through 12 November 1941), the actual number of corpses cremated (677), the actual consumption of coal (20,700 kg) for these cremations, and the minimum duration of the cremations (221 hours and 30 minutes, or 13,290 minutes). At that time, all the conditions favoring multiple cremations in one muffle existed at Gusen, viz.:

- The furnace had been inactive between 16 and 25 October because of repair work, which meant that the corpses of detainees who had died in the meantime were piling up in the morgue and it was most urgent to dispose of them.
- The furnace was restarted under the supervision of a specialist, the Topf technician August Willing, who stayed at the crematorium until 9 November.[518]

[518] Topf, *Bescheinigung über besondere Berechnung geleisteter Tagelohn-Arbeiten for Bauleitung der Waffen-SS und Polizei Gusen*, 12 October – 9 November 1941. BAK, NS 4/Ma 54.

The basic data set out above can refer only to two possible scenarios: Either only single cremations were carried out or multiple cremations.

1. In the first case, we would have 677 cremations in 13,290 minutes in two muffles, *i.e.*, in rounded figures, 338 cremations in 13,290 minutes in one muffle, hence some 40 minutes for one cremation in one muffle.
2. In the second case, assuming that two corpses were loaded jointly into each muffle in each case, 338 such double cremations would have taken place in the two muffles and lasted 13,290 minutes altogether, *i.e.* 169 double cremations in a single muffle over 13,290 minutes, the equivalent of a double cremation lasting 80 minutes in a single muffle. The same reasoning is valid for the coke consumption.

Thus, if the above data refer to double cremations, the duration of the cremation of each such load would have required 80 minutes and the capacity of the furnace would not have been affected.

9.2.3. Documents on Multiple Cremations

On 4 February 1944, Hans Kori sent the following letter to the Waffen SS and Police PoW camp at Lublin Majdanek:[519]

> *"Re: Crematorium*
> *In addition to our report of today's date concerning the operation of the incineration furnaces at Konz.-Lager Lublin, we wish to inform you that, in the case of the operation of stationary crematoria, the fuel requirements can be reduced to a very low consumption if observation of the operation is carried out properly, because the load to be incinerated contributes to fuel savings on account of its good combustibility, if the temperature of the crematorium is around 700°C.*
> *For the fuel supply for a given heating period one may assume that for preheating the furnace 50 kg of coke are required, in addition to 25 kg of coke for each incineration. For 10 incinerations in one day, this leads to a total consumption of some 300 kg. It is of no importance whether coke is used exclusively or a mixture of coke and hard coal is used. In the latter case, one would operate with a mixture of 150 kg* [of coal] *and 150 kg* [of coke]. *An equal amount of 300 kg for one day would also allow 20 incinerations to be handled easily, if one abandons individual introductions."*

The coke consumption stated for one cremation – 25 kg – confirms with satisfactory accuracy the consumption at Gusen. The fact that the fuel requirements were calculated for ten cremations in each muffle (or a total of 50 cremations per day) means that the duration of one cremation was at least one hour (two hours of preheating plus tne hours of cremation = one operating day of 12 hours).

The reference to abandoning "individual introductions" (*Einzeleinführungen*) alludes to the simultaneous introduction of two corpses into one muffle, which would bring about fuel savings of 50%, *i.e.* ([300–50]÷20=) 12.5 kg of coke for each corpse. Yet the man responsible for this crematorium, *SS Haupt-*

[519] APMM, sygn. VI-9a, Vol. 1, p. 27; cf. Document 261.

scharführer Erich Mussfeldt, declared with respect to the new crematorium at Majdanek during the Krakow Trial of the Auschwitz camp garrison:[520]

> *"Only one corpse was introduced into each muffle, its cremation lasted one hour."*

This duration, as we have seen, is confirmed by numerous sources and documents and is therefore reliable.

Also, one cannot imagine that Hans Kori would have made a statement which was in direct disagreement with the performance of his own furnaces for the cremation of animal carcasses.

To the above letter, a report of the same date was attached on the subject of the crematoria. In it, Kori explained the reasons for some problems encountered in the operation of the furnaces:[521]

> *"But if, on opening the hearth doors, a bright flame juts forth from the slots of the smoke dampers, this is caused by the pressure of 'false air.' It is merely necessary to fill the unnecessarily wide air gaps around the damper plates in order to prevent both cold air from entering the furnace and the appearance of such flames."*

This inconvenience was due to the fact that it had not been technically possible to manufacture refractory dampers which could be hermetically closed – a gap of 4.5 mm[522] remained through which cold air entered into the smoke duct. Another problem concerned the temperature of the muffle:

> *"If, as was noted during the trial runs, the temperature in the forward portion of the incineration chamber, i.e. directly behind the introduction door, is not high enough for a rapid incineration of the material placed at this point, this, too, is caused primarily to the leakage of 'false air'* [into the muffle]*."*

According to Kori, this inconvenience would also disappear with the elimination of the gaps mentioned above.

We should underline the fact that, if a temperature of 700°C in the front part of the muffle could not be maintained simply because "false air" entered the smoke duct, the introduction of two normal corpses into the muffle would have brought about an even-greater temperature drop during the evaporation phase, with a significant degradation of the performance of the cremations.

If it took one hour and 25 kg of coke to cremate a single corpse, an unchanged coke consumption in the case of two corpses would indicate that such a double-cremation would also have lasted only one hour, but this is in disagreement with the practical results discussed above.

The hypothetical statement contained in the above letter is thus completely discredited by the facts.

The document in question is the typewritten copy ("*odpis*") of a (probably likewise) typewritten German copy ("*Abschrift*") prepared at the request of the Polish-communist prosecutor Jan Grzybowski at an unknown point in time.

---

[520] APMO, ZO, sygn. D-pr-20/61a, p. 76: "*Do jednej retorty wkładano tylko jedne zwłoki, spalenie ich trwało około 1 godziny*."

[521] Attachment to the letter from Hans Kori to *Kommandantur* of *KL* Lublin dated 4 February 1944. APMM, VI-9a, Vol. 1, pp. 25f.

[522] The text actually states 45 mm, but that is probably an error.

Neither the original nor even the German-language copy has been published, and one must therefore regard the Polish-language version with great suspicion.

There is also a Topf document on the subject of the concurrent introduction of several corpses into a muffle, the letter of Fritz Sander of 14 September 1942 already mentioned (Section 7.4.1.):

Illustration 4: Muffle door of the Topf double-muffle furnace at the Mauthausen Camp, identical to those of the double-, triple- and 8-muffle furnaces at Auschwitz. © C. Mattogno

> *"As a makeshift solution, one has tried to use a series of furnaces or muffles and by loading them with more corpses, but this does not solve the basic problem, i.e. the drawbacks of the muffle system. These drawbacks of the muffle furnace, which cannot be solved even by assembling multiple-muffle furnaces (triple- or 8-muffle furnaces) and loading more corpses into the individual muffles, are in my judgment the following:"*

Sander greatly underestimated the problem of introducing multiple adult male corpses[523] into a muffle. The loading system of the double- and triple-muffle furnaces was in fact constrained by the dimensions of the muffles' introduction openings, which measured 60 cm × 60 cm, with the lower half having the shape of a 30 cm × 60 cm rectangle, while the upper half was a semicircle with a radius of 30 cm.

Illustration 4 gives all the relevant measurements. The top part of the introduction stretcher, whose side tubes ran over the guide rollers, was 12 cm above the bottom of the muffle door and the refractory grate; the two horizontal lines show the height of a first (18 cm) and a second emaciated corpse (18 cm) introduced one on top of the other into the muffle; the remaining space clearly would have been insufficient for a third emaciated corpse. Loading the second corpse sideways (with the shoulder line vertical instead of horizontal), and then a third one horizontally, would have required the tilting of the stretcher by at least 45°, an extremely complicated operation, not to say impossible. It is clear that the simultaneous loading of two normal corpses would have at least presented great difficulties; introducing three or four corpses at once would have been absolutely impossible.

[523] It should be kept in mind that back then, the future Crematorium II was still planned for a PoW camp for 125,000 Soviet PoWs, which would have included no women or children. The capacity indicated in the "Explanatory report for the preliminary project for the new construction of the *Waffen-SS* PoW camp at Auschwitz, Upper Silesia," of 30 October 1941 (60 corpses in one hour, hence four corpses per muffle in one hour; cf. Document 211) is impossible already because of the insurmountable problems of loading the muffles as shown here.

From Sander's letter we can glean that "the cremation did not proceed quickly enough to ensure the elimination of a great number of corpses at a desirably high rate" even when "loading more corpses into the individual muffles," clearly meaning such multiple cremations evidently did not produce appreciable improvements with respect to productivity of cremations.

9.2.4. Thermal Inadequacy during Water Evaporation

The essential condition for good cremation performance is that the muffle temperature never drops below 600°C, because below that temperature the corpses merely carbonize, but are no longer cremated.

Let us look at the heat phenomena associated with a triple-muffle furnace in the normal case of the cremation of a single adult corpse in each muffle, and in the hypothetical case of two corpses per muffle.

Single Adult Corpse

A body of 70 kg contains, on average, some 45.5 kg of water. Hence the energy needed to heat, vaporize and superheat this water from 10°C to 600°C for three corpses is (cf. p. 124):[524]

$$3 \cdot 45.5\ \text{kg} \cdot [633\ \text{kcal kg}^{-1} + 0.487\ \text{kcal kg}^{-1}\text{°C}^{-1}(600\text{°C} - 100\text{°C})] \approx 119{,}600\ \text{kcal} \quad [111]$$

The evaporation process, as determined experimentally, required about one-half hour. The coke throughput rate for the triple-muffle furnace was 70 kg/hr (two hearths with a throughput rate of 35 kg/hr each), hence the theoretical heat available in half an hour was 6,470 kcal/kg × 35 kg = 226,450 kcal.

The heat actually available was much less, because much of the heat produced in the gasifiers was lost. In the evaporation phase, the most-important heat losses were those by radiation and by conduction, which amounted to about 62,500 kcal/hr at 800°C, and which we may assume to be around 46,900 kcal/hr at 600°C, or 23,450 kcal in half an hour. This corresponds to (23,450/226,450 × 100 =) 10.3%. The sensible heat of the exhaust gases at 600°C can be calculated to be 31.3%. The unburnt gases contributed 4%, and the incombustibles on the hearth about 3.1% to the total loss.

The efficiency of the furnace was therefore (100 – [10.3 + 31.3 + 4 + 3.1] =) 51.3%. Hence the effective yield of the coke was (6,470 × 0.513) ≈ 3,320 kcal, and the available heat was (35 kg × 3,320 kcal/kg =) 116,200 kcal. To maintain the furnace at 600°C, a heat supply of (116,200 – 119,600 =) 3,400 kcal would therefore have had to be provided by the radiation from the muffle walls, where it was readily available in this phase of the process.

Two Adult Corpses

Let us now examine the second case. All values go up by a factor of two with respect to the previous case. The water content of the corpses would be 273 kg, and the heat of vaporization at 600°C about 239,200 kilocalories.

---

[524] On average 0.487 kcal kg^{-1}°C^{-1} between 100°C and 600°C; see www.engineeringtoolbox.com/water-vapor-d_979.html.

Available heat remained constant at 116,200 kcal in 30 minutes, hence the heat deficit is (116,200 – 239,200=) 123,000 kcal or 41,000 kcal per muffle. Would the radiation from the muffle walls have been enough to make up for this deficit? It is difficult to establish precisely the heat supply to the corpse from the radiating muffle, both for reasons of geometry and because of the progressive cooling of the muffle wall.

The problem was treated in the 1930s in a specific article by Professor Schläpfer, one of the most-eminent specialists in the field of cremation at the time, and the article provides us with a credible estimate of the heat radiated from the muffle walls onto a corpse at various wall temperatures. Schläpfer gives a chart, from which we can draw the data given in the following table (Schläpfer 1938, p. 153; cf. Mattogno 2019, Document 47, p. 651):[525]

Temperature of muffle walls	Heat radiated onto the corpse (per Schläpfer)
800 °C	1,400 kcal/min
700 °C	930 kcal/min
600 °C	600 kcal/min
500 °C	360 kcal/min

In the case of radiation towards a hypothetical load of two corpses in one muffle, the geometry obviously changes. Most importantly, the surface/volume ratio of such a load would be less favorable than for a single corpse, because the two corpses would cover each other partly. But even aside from this consideration, the heat required to evaporate and superheat the water contained in two corpses, ca. 79,700 kcal, would become available only over a period of (79,700 kcal ÷ 600 kcal/min =) some 130 minutes at a constant temperature of 600°C. However, the wall temperature of the muffle would not stay constant for such a long time but would drop rather significantly. Hence the thermal conditions would soon become very unfavorable, because, as we can see from Schläpfer's chart, the radiation heat flow drops rapidly with decreasing surface temperatures. At 500°C, the heat transfer would be cut to a mere 60% of the value at 600°C.

The engineer Hans Kori, speaking about a similar problem, noted (Kori 1924, p. 117):

> *"If the internal wall of the cremation chamber has a surface area of about 4 m² with a specific gravity of 2.1, a layer 5 cm in thickness weighs about 420 kg. Specific heat of refractory is about 0.2* [kcal kg^{-1} $°C^{-1}$]*; if a layer of 5 cm were to give up its heat in a sufficiently rapid and complete manner, with a temperature drop from 1000° to 800°*[C]*, its heat contribution would be only 200 × 0.2 × 420 = 16,800* [kilo]*calories. Actually, not even this is possible, because the wall does not release the stored heat as fast as the temperature drops."*

In the triple-muffle Topf Furnace, the weight of the radiating brickwork of one muffle was about (0.15 m thick × 5 m² surface × 2,000 kg/m³ density =) 1,500 kg. In order to supply the heat lost by the evaporation of the water from two

[525] Radiation heat transfer is proportional to the fourth power of the temperature difference, cf. http://www.engineeringtoolbox.com/radiation-heat-transfer-d_431.html.

corpses, each muffle would have had to contribute 79,700 kcal, which would mean that the average wall temperature of the muffles would have had to drop by (79,700 kcal ÷ 0.2 kcal kg^{-1} $°C^{-1}$ ÷ 1,500 kg =) about 265°C. Hence, if the muffle temperature had been at the required 800°C during the introduction of the corpses, it would have dropped down to some 535°C during the evaporation phase, slowing the evaporation process drastically.

Of course, the massive heat loss of the muffle walls during the evaporation of the corpse water would have had to be compensated for later on. In order to re-establish the thermal conditions for subsequent cremations, a period of re-heating would therefore have been required. The heat supplied to each muffle in one minute was:[526]

$$\frac{3{,}320 \text{ kcal/kg} \cdot 70 \text{ kg/hr}}{3 \cdot 60 \text{ min/hr}} = 1{,}291 \text{ kcal/min} \qquad [112]$$

Hence 79,700 kcal ÷ 1,291 kcal/min ≈ 62 minutes or one hour would have been needed to get the muffles back into thermal shape for the next load.

I have simplified here the evaporation process, which is more-complex in reality, because other factors come into play, but these factors apply in the same way both to individual and to multiple cremations; therefore, the enormous difference of the order of magnitude of the heat involved in each case remains valid as calculated and demonstrated.

The Topf design of the triple- and 8-muffle furnaces was also inadequate for simultaneous multiple cremations not only for the reasons of thermodynamics set out above. In addition, the introduction of two or three corpses into a muffle would have caused an obstruction of the combustion-gas flow through the three openings which connected the lateral muffles to the center muffle in the triple-muffle furnace or those linking the inner to the outer muffles in the 8-muffle furnace. Several corpses placed on the refractory grate of the center muffle in the triple-muffle furnace or on that of the lateral muffles of the 8-muffle furnace would have, moreover, partially blocked the slots between the grate bars, impeding the flow of the combustion gases toward the flue ducts. This would have led to a decrease in the draft of the chimney and that of the gasifier with a corresponding decrease in the heat supply to the muffle.

Furthermore, the introduction of several corpses into a single muffle would have reduced the free muffle volume. As a result, the dwell time of the combustion gas flowing through the muffle would have been reduced to the point where it would have partially burned in the smoke duct rather than in the muffle, resulting in a lower heat transfer to the corpse and the muffle walls, resulting in even-lower temperatures during the evaporation phase, and potentially causing heat damage to the flue ducts.

All this proves that the triple- and 8-muffle furnace were conceived for the cremation of one corpse at a time in each muffle and that the introduction of two or more corpses into a muffle would inevitably have extended the duration

[526] 3,320 kcal/kg: effective heating value of coke; 70 kg/hr: coke consumption of the two gasifiers; 3: number of muffles.

of the cremation considerably more than by the simple factor contributed by the number of corpses introduced, *i.e.* considerably more than twice as long for two corpses.

9.2.5. Thermal Overload during Main Combustion

The concurrent cremation of several normal corpses in one muffle brings into focus another insurmountable thermal problem: the increased thermal load on the combustion chambers (muffle and ash chamber) during the main combustion phase of the corpses after their water has evaporated.

The refractory walls of a combustion chamber can be damaged by slag and molten ash, and their temperature must therefore be kept below the melting point of slag and ash, which, as we have seen, normally lies between 1100 and 1200°C. If such a temperature is reached, encrustations and adhering particles will form on the grates and the walls as well as along the flue ducts. Such fouling will affect the geometry of the furnace and result in a lowered performance.

The problem is of particular importance in the design of solid-fuel hearths for boilers.[527] The specific thermal loads used for the design of coal-fired combustion plants vary greatly, depending on the combustion system used, the type of fuel, and the type of combustion chamber. In practical design work, the thermal loads permitted for powdered-coal firing, over a very wide range of sizes, is between 100,000 and 200,000 kcal m^{-3} hr^{-1}. Thermal loads of gas-fired installations are normally the following:

For lean gases	150,000 kcal m^{-3} hr^{-1}
For methane	140,000 kcal m^{-3} hr^{-1}
	170,000 kcal m^{-3} hr^{-1}
For rich gases	220,000 kcal m^{-3} hr^{-1}
	300,000 kcal m^{-3} hr^{-1}

For steam generators with an average output of 2,500 kg hr^{-1}, one may use specific thermal loads of 150,000 kcal m^{-3} hr^{-1} for the combustion chambers (all data from Fornasini 1960, pp. 225, 232f.).

For urban-waste incinerators "the volume of the combustion chamber, including the volume of a possible post-combustion chamber, must be such that the specific thermal load does not exceed a value of 630,000 kJ m^{-3} hr^{-1} (150,000 kcal m^{-3} hr^{-1}) in normal continuous operation" (*Manuale*... 1990, p. E740). We may hence base ourselves, for the triple-muffle furnace, on a maximum thermal load of 150,000 kcal m^{-3} hr^{-1} or 225,000 kcal hr^{-1} for the combustion chamber (muffle and ash chamber).[528]

Theoretically, for each one of the outer muffles, we have a heat supply of (23.5 kg/hr × 6,470 kcal/kg) ≈ 152,050 kcal/hr from the coke combustion plus 146,100 kcal/hr from the combustion of the corpse, for a total of 298,150 kcal/hr. Actually, however, part of the heat of the coke is lost with the unburnt

[527] Cf. in this respect ter Linden 1935, who gives a detailed calculation of the hearth walls and discusses various systems for cooling them.

[528] The volume of the combustion chamber was ≈ 1.5 m^3.

materials (6.8% ≈ 9,900 kcal/hr), another loss is brought about by the heat lost through radiation and conduction (calculated to be ≈ 22,500 kcal/hr for each of the two outer muffles), and finally part of the available heat is taken up by the evaporation of the corpse water (≈46,300 kcal/hr). Adding the various other losses entering into the heat balance – some 28,000 kcal/hr – we see that the actual heat supplied does not exceed (298,150 – 9,900 – 22,500 – 46,300 – 28,000 =) 191,450 kcal/hr, or ≈ 127,600 kcal m^{-3} hr^{-1}.

The effective heat produced by the corpse is (146,100 – 46,300 – 11,400 – 9,900 =) 78,500 kcal, that produced by the coke is (191,450 – 78,500 =) 112,950 kcal.

Even if we assume that the heat from the corpse is produced entirely during the last half-hour, the maximum heat generation would be ([78,500×2] + [112,950÷2]) ≈ 213,500 kcal per hour and per combustion chamber, or (211,850÷1.5) ≈ 142,300 kcal m^{-3} hr^{-1}, which confirms that the maximum heat load was around 150,000 kcal m^{-3} hr^{-1}.

On the basis of what has been stated above, we can see that the simultaneous cremation of two normal corpses in each one of the two lateral muffles would, in any case, have required twice as much fuel and considerably more than twice the time. *If*, hypothetically speaking, the cremation of two corpses had taken place within only one hour, with a main combustion phase of one half-hour, then the maximum amount of heat so generated during the main combustion phase would have been (141,200×2 =) 282,400 kcal m^{-3} hr^{-1}, or nearly twice the permissible thermal load. This would have inevitably damaged the furnaces in the long run.

9.3. Soviet and Polish Technical Investigations

After the occupation of the concentration camps in Eastern Europe, the Soviets set up a number of "Commissions of Inquiry," which produced, *i.a.*, technical reports on the cremation furnaces at such locations. I will present the full translation of the investigations concerning the furnaces at Majdanek and Sachsenhausen, and brief excerpts from the report on the furnace at the Stutthof Camp. A detailed description of the furnaces will follow in Sections 11.2.5/6. The report on Majdanek was written in August of 1944, the one on Sachsenhausen in June of 1945, and the one on Stutthof in May of 1945.

9.3.1. The Soviet Report on the Kori Cremation Furnaces at *KL* Lublin-Majdanek

"Productivity of the cremation furnaces.
The cremation capacity of the cremation furnaces depends on:
1) the temperature of the cremation chamber
2) the time needed for loading
3) the amount of corpses loaded
4) the cremation time of a single load

1. The temperature in the cremation chamber
The cremation chamber, lined with standard refractory,[529] *was designed for a temperature of 1300-1400°C. On inspection, the blocks of the cremation furnaces showed: in all cremation chambers, the standard brickwork presented noticeable fusion, and the standard* [refractory] *bricks of the grate bars* [of the hearth] *showed intensive fusion of the ash and a change*[530] *of the silica. The cast-iron dampers of the horizontal* [smoke] *collection duct are deformed in their lower part on account of fusion.*
The fusion of the standard refractory of the cremation chambers and the changes in the silica demonstrate that the temperature of the cremation chamber was higher than 1500°C. The deformation and fusion of the cast-iron dampers demonstrate that the temperature of the off-gases was around 1200°C.
2. The time needed to load the corpses into a chamber.
Loading of corpses into the cremation chamber could be carried out from only one side of the block of cremation furnaces. At the time of inspection of the block of cremation furnaces, some corpses with their limbs cut off and heavily damaged by fire were encountered on the loading side of the cremation chambers, which indicates a preliminary piling up of corpses in the space in front of the furnaces to speed up the loading [operation].
The iron stretchers in front of the furnaces were used only to load the corpses into the cremation chambers, which is confirmed by the presence of rails and rollers in front of each furnace.
On account of the high temperature of the furnaces, loading of the corpses may have been carried out in the following manner:
a) the corpses were laid out on the iron stretcher placed on the rails and the rollers;
b) the doors of the cremation chamber were opened;
c) the corpses on the stretcher were pushed via the rollers toward the [grate] *bars and then placed on the* [grate] *bars of the cremation chamber by means of a rod.*
All the operations for loading the furnaces outlined above, with a pile of 'treated'[531] *corpses in front of each cremation chamber, could be executed within 2 to 3 minutes.*
3. The quantity of corpses loaded into one cremation furnace.
The presence, at the time of the inspection, of a large amount of bone ash in the cremation chamber, in the space below the bars of the hearth and on the bars of the hearth [used] *for heating the furnaces, as well as that of a pile of corpses with their limbs cut off and in front of the line of furnaces, demonstrates the simultaneous combustion of several corpses in each furnace. In practice, two complete corpses or four corpses with their limbs cut off could be loaded into each furnace.*

---

529 *Dinasovo*, literally: in accordance with DIN norms (DIN = *Deutsches Institut für Normung*, German Institute for Standardization). It is a word coined by the Soviet experts on the basis of the abbreviation DIN.
530 *Pererogdenie modifikatsii,* litterally "denaturation of the [silica] modification."
531 *I.e.* with their limbs cut off.

4. The time needed for the cremation of a single load of corpses.

In order to establish the time needed for the complete cremation of the corpses, we will take as a base for calculation the cremation of one corpse in one furnace. We will assume:

a) a human body contains 66% of water, 1.1% of carbohydrates, 27.3% of fat and protein, and 5.6% of ash;

b) on a weight basis, assuming the weight of an emaciated corpse to be 50 kg [we have] *33 kg of water, 0.6 kg of carbohydrates, 13.65 kg of fat and protein and 2.8 kg of ash;*

c) the organic part, essentially fat and protein, is made up roughly by carbon and hydrogen in a ratio of 4:1, i.e. 80% carbon and 20% hydrogen, leaving aside the oxygen content of the carbohydrates as well as the sulfur and nitrogen in the organic portions because of their insignificant weight.

Therefore, a body contains 11.2 kg of carbon and 2.8 kg of hydrogen.

In the course of the combustion of the corpse, 11.2 kg of carbon will produce 41 kg of carbonic [acid] *anhydride, 2.8 kg of hydrogen and 25 kg of water (vapor).*

For the combustion of 11.2 kg of carbon, a theoretical amount of 29.5 kg of oxygen is required, and for 2.8 kg of hydrogen, 22.3 kg of oxygen. Hence, a total amount of 51.8 kg of oxygen is required.

Assuming the combustion of the corpse to be carried out with an excess air [ratio] *= 1.3, a total of 67.4 kg of oxygen would be needed.*

Such an amount is associated with 225.9 kg of nitrogen in air.

The composition by weight of the combustion products generated during the cremation is as follows:

water vapor	*58.2 kg*
carbonic anhydride	*41.6 kg*
oxygen	*15.6 kg*
nitrogen	*225.9 kg*

or, in volumetric terms:

water vapor	*72.4 m³*
carbonic anhydride	*21.2 m³*
oxygen	*10.9 m³*
nitrogen	*180.9 m³*

In total, the cremation of one corpse produces 285 m³ of combustion products.

Under normal conditions, we assume an exit temperature for the cremation products leaving the chimney of 400°C. At that temperature, the volume of smoke from one corpse is about 685 m³.

On the basis of the attached chart, which shows the cremation time required in various cremation furnaces as a function of temperature, [we have] *a cremation time for one corpse in a furnace with standard lining, with a temperature of the cremation chamber of 1400°C, of not more than 20 minutes.*

Assuming, for the smoke in the smoke channel – without a forced draft – a velocity of 3 m/sec and an operation of both furnaces at the same time, the cross-sectional area of the lower part of the smoke duct is 0.36 m², which is in agreement with the cross-sectional area of the smoke duct of the cremation furnaces inspected in the concentration camp of the City of Lublin, without taking into account the two powerful ventilators present with a capacity of 168 m³ per minute.

The simultaneous operation of the two ventilators induced a considerably more-rapid progress of the cremation and allowed to maintain a temperature in the cremation chamber [not] *lower than 1500°C at full load.*
Therefore, taking into account the attached chart for the determination of the cremation time, we conclude that the cremation of the corpses did not take longer than 10-12 minutes.
Our calculation is also confirmed by the fact that with a [forced] *suction of the fumes the furnace operated in an abnormal manner because of the absence of temperature differences, as we can see from a letter dated 8 January 1943 by the H. Kori Co. and addressed to* Hauptamt *CIII of the* Reichsführer *SS and Chief of the German Police in connection with the crematorium of the concentration camp at the City of Lublin. In this letter, it is recommended to install large devices for the production of hot water in order to ensure proper control of the smoke temperature.*
On the basis of the above calculations, we see that:
a) the temperature of the cremation chambers was maintained at 1500°C;
b) cleaning of the lower container and loading the furnace with corpses did not take more than 3 minutes;
c) four 'treated' corpses including their cut off limbs could be loaded simultaneously into one furnace;
d) the time needed to cremate one load was less than 12 minutes.
Hence, for an operation of the cremation furnaces over 24 hours, their cremation capacity in 24 hours was

$$\frac{24 \times 60 \times 4 \times 5}{15} = 1{,}920 \text{ corpses.} \qquad [113]$$

The president of the commission of experts
Architectural Engineer Krauze
Members:
Engineer, Major, Instructor Telyaner,
Engineer, Major, Instructor,Candidate in Technical Science Grigor'ev."[532]

9.3.2. The Soviet Report on the Kori Cremation Furnaces at *KL* Sachsenhausen

"Capacity of the cremation furnaces.
The cremation capacity of cremation furnaces depends:
1. on the temperature of the cremation chamber,
2. on the time needed for loading the furnace,
3. on the number of corpses loaded into the furnace
4. on the duration of the cremation of a single load.
1. The temperature of the cremation chamber.
The cremation chambers were lined with standard refractory bricks and were designed for a temperature of 1400-1450°C. Inspection of the block of the cremation furnaces in the crematorium showed that in all cremation chambers the standard [refractory] *brickwork did not show considerable fusion and that the*

[532] GARF, 7021-107-9, pp. 245-249. The original text of the report is published in Graf/Mattogno, p. 318.

standard [refractory] *bricks of the bar grate* [of the hearth] *showed minor fusion of the ash and a very small alteration of the silica. All this goes to show that the temperature in the furnaces of the stationary crematorium did not exceed 1200-1300°C.*

The furnaces of the mobile crematoria worked with forced draft. Inspection of these furnaces revealed that in all cremation chambers the standard [refractory] *brickwork showed minor fusion and slag with a surface covering of inorganic salts, and that the standard* [refractory] *bricks of the* [hearth] *grate showed profound fusion of the ash and an alteration of the silica.*

All of this demonstrates that the temperature of the cremation chamber was not maintained below 1400°C.

2. The time needed for loading one [cremation] *chamber with the corpses.*

Loading of the corpses into the cremation chamber could be effected only from one side of the aligned row of furnaces, in the following sequence:

a) the corpses were placed on an iron stretcher;

b) the doors of the cremation chamber were opened and the gate was raised;[533]

c) the corpses on the stretchers were pushed via a series of rollers into the cremation chamber and were arranged on the standard bars by means of an iron rod;

d) the gate was lowered and the doors were closed.

The execution of all loading operations of the furnaces as described above did not require more than 5 minutes.

3. The number of corpses loaded.

Within 5 minutes it was possible to load 4-6 corpses into the cremation chamber of the furnace, depending on their sizes, according to the sketch attached:

(6) Sketch showing the maximum
(5) (4) manner of loading of a cremation
(3) (2) (1) chamber

4. The time needed for the cremation of a single furnace load.

In order to determine the time needed for the complete cremation of the corpses, we will base ourselves on the indicative chart for the determination of the cremation times in various cremation furnaces as a function of temperature, on file.

From the chart, we can see that the cremation of a single load of corpses in the furnaces lined with standard [refractory] *bricks, for a temperature of 1200°C in the cremation chamber, was about one hour. At a temperature of 1400°C it was half of that, i.e. about 30 minutes.*

C. Calculation of the cross-sectional area of the chimney ducts for the purpose of control.

For the verification of the [cross-sectional area] *of the smoke ducts for the off-gases of the combustion products we will assume:*

a) a human body contains 66% of water, 1.1% of carbohydrates, 27.3% of fat and protein and 5.6% of ash;

b) on a weight basis, assuming the weight of an emaciated corpse to be 50 kg [we have] *33 kg of water, 0.6 kg of carbohydrates, 13.65 kg of fat and protein and 2.8 kg of ash;*

---

[533] The refractory closure of the muffle (*Schamotteabsperrplatte*); cf. Chapter 11.

c) assuming that the organic part, essentially fat and protein, is made up roughly by carbon and hydrogen at a ratio of 4:1, i.e. 80% carbon and 20% hydrogen, leaving aside the oxygen content of the carbohydrates, as well as the sulfur and nitrogen in the organic portions because of their insignificant weight.
Therefore, a body contains 11.2 kg of carbon and 2.8 kg of hydrogen.
In the course of the combustion of the corpse, 11.2 kg of carbon will produce 41 kg of carbonic [acid] *anhydride, 2.8 kg of hydrogen and 25 kg of water (vapor).*
For the combustion of 11.2 kg of carbon a theoretical amount of 29.5 kg of oxygen is required, and for 2.8 kg of hydrogen 22.3 kg of oxygen. Hence, a total amount of 51.8 kg of oxygen is required.
Assuming the combustion of the corpse to be carried out with an excess air [ratio] *= 1.3, a total of 67.4 kg of oxygen would be needed.*
Such an amount is associated with 225.9 kg of nitrogen in air.
The composition by weight of the combustion products generated during the cremation is as follows:

water vapor	*58.2 kg*
carbonic anhydride	*41.6 kg*
oxygen	*16.6 kg*
nitrogen	*225.9 kg*

or, in volumetric terms:

water vapor	*72.4 m³*
carbonic anhydride	*21.2 m³*
oxygen	*10.9 m³*
nitrogen	*180.8 m³*

In total, the cremation of one corpse produces 285 m³ of combustion products.
For one furnace, assuming a single load of 6 corpses, we have 285 × 6 = 1,710 m³ of combustion products.
Furthermore, the cremation of 6 corpses requires 60 kg of coke – or, in the mobile furnaces, 42 kg of oil.
During the combustion of coke, 790 m³ of combustion products are formed, if we assume an excess air [ratio] *= 1.3.*
Thus, for one furnace:

$$1{,}710 + 790 = 2{,}500 \text{ m}^3 \text{ of combustion products,}$$

for two furnaces: 2,500 × 2 = 5,000 m³/hr.
If we assume a combustion temperature at the entrance of the chimney ducts of 1000°C and a smoke-flow rate of 3 m/sec, the lower cross-section of the chimney duct is

$$\frac{5{,}000/273 + 1/273 \times 1{,}000}{3{,}600 \times 3} = \frac{23{,}000}{3{,}600 \times 3} = 2.1 \text{ m}^2.\text{[534]} \qquad [114]$$

This corresponds to an effective cross-sectional area of half of a chimney duct – 2.0 m² – and enables the simultaneous cremation of 12 corpses in one hour or 24-25 corpses in 4 furnaces.

---

[534] The equation used here is wrong, and it does not result in 2.1 m² either. The proper equation would be $\frac{5{,}000 \text{ m}^3/\text{hr} \cdot (1 + 1{,}000°\text{C}/273°\text{C})}{3{,}600 \text{ sec/hr} \times 3 \text{ m/sec}} = 2.16 \text{ m}^2$.

If the stationary furnaces were in continuous operation, the crematorium could cremate 4 × 6 × 24 = 576 corpses per day.
In continuous operation of the mobile furnaces [as well]*, one could thus cremate*

$$\frac{3 \times 6 \times 60 \times 24}{30} = 864 \text{ corpses per day.} \quad [115]$$

The experts: Engineer, Major Telyaner
Engineer, Major Grigor'ev."[535]

9.3.3. The Soviet Report on the Kori Cremation Furnaces at *KL* Stutthof

The Soviet report on the Kori Furnaces at *KL* Stutthof is part of a more-extensive report on the general situation in this camp, dated 14 May 1945, from which we have selected the following pertinent passages:[536]

"The internal volume of a cremation furnace is 0.5 × 0.5 × 3.2 = 0.96 m³. Considering the extreme state of meagerness of the corpses which caused one corpse to occupy, on average, a space of 0.25 × 0.2 × 1.56 = 0.8 m³, the furnace could contain 0.96 ÷ 0.8 = 12 corpses. Running it at full capacity, one could therefore lodge 12 corpses in the furnace, introduced lengthwise in two layers. The design of the furnace allowed it to reach 900 – 1,000°C with coke firing, and at those temperatures the cremation process took 56-60 minutes. […]
In the concentration camp, there were three cremation furnaces. Starting from the assumption that, as stated, 12 corpses could be introduced at one time, that the cremation process lasted 50 minutes and that 10 minutes were needed to load the furnace, we find a total cremation capacity of

$$\frac{24}{1} \times 12 \times 3 = 864 \text{ corpses in 24 hours.} \quad [116]$$

If the temperature is lower, i.e. 450-500°C, the cremation process naturally takes twice as long, or one hour and forty minutes, and we would thus have a capacity of

$$\frac{24}{2} \times 12 \times 3 = 432 \text{ corpses."} \quad [117]$$

9.3.4. Discussion of the Soviet Reports on the Kori Furnaces

The reports assume that the cremation capacity depended on four factors:

1. the temperature of the cremation chamber;
2. the time needed for loading the furnace;
3. the number of corpses loaded into one cremation chamber;
4. the duration of the cremation of one load of corpses.

As these factors are interdependent, we must examine them together.

The Soviet experts claim that the coke-fired furnaces at Majdanek normally operated at a temperature of 1,500°C; those at the Sachsenhausen crematorium

---

[535] GARF, 7021-104-3, pp. 26-31.
[536] "Minutes of the technical report on the SS concentration camp at Stutthof," 14 May 1945. GARF, 7021-106-216, pp. 5f.

at 1,200 to 1,300°C (for the 4 coke-fired furnaces) or at 1,400°C (for the 2 oil-fired furnaces). These statements are technically unsound. On this subject, the engineer Richard Kessler noted (Kessler 1930, p. 136):

> *"Introduction temperatures of 1,200-1,500°C, as they often appear in reports on the operation of crematoria (in the journal 'Die Flamme', a temperature as high as 2,000°C was reported) are probably estimated values which, however, were never measured. At such temperatures, both the refractory and the bones would melt and adhere to each other. At the Dessau Trials, the most-suitable temperatures were found to be between 850 and 900°C."*

As far as the Majdanek Furnaces are concerned, I have already noted that initially, in the front portion of the cremation chamber, it was not possible to maintain a temperature even as low as 700°C because of the entry of false air into the flue duct through a gap of 4.5 mm. A "normal" operation at a temperature of 1,500°C can have no factual basis, nor technical possibility. Furthermore, the refractory wall of these furnaces showed completely negligible traces of melting (cf. Section 11.2.6.). Hence the statements of the Soviet experts have no foundation in reality.

The Soviet experts derived the duration of cremations from a self-concocted "indicative chart for the determination of the combustion time of corpses in various cremation furnaces as a function of temperature" (Document 262), which has the "time in minutes" as its ordinate and as its abscissa the "temperature in °C." This chart starts at a muffle temperature of 800°C and goes up to a temperature of 1,500°C. The relationship between temperature and duration of cremations is shown as follows:

800°C:	120 min.	1. (Klingenstierna Furnace)
900°C:	105 min.	
1,000°C:	90 min.	2. (Siemens Furnace)
1,100°C:	75 min.	
1,200°C:	60 min.	3. (Schneider Furnace)
1,300°C:	45 min.	
1,400°C:	30 min.	
1,500°C:	15 min.	

We do not know the sources from which these specifications were drawn, but it is certain that, for temperatures in excess of 1,000°C, these data are completely untrustworthy.

The chart in question assigns to the Klingenstierna Furnace a duration of 120 minutes for a temperature of 800°C, as against 90 minutes at 1,000°C for the Siemens Model and finally 50 minutes at 1,200°C for the Schneider Furnace. As I have explained in Chapter 3 of Unit I of this study, the three above devices all operated on the principle of indirect cremation employing hot air: the regenerators or recuperators, after having been heated to 1,000°C, were fed atmospheric air that entered the muffle at the listed temperature and then caused the combustion of the corpse. According to Architect Beutinger, the duration of a cremation was 90 minutes for the Siemens Furnace at Gotha operating at 900°C, 60 to 90 minutes for the Klingenstierna Furnaces operating at 1,000°C, and 45 to 90

minutes for the Schneider Furnaces, which reached 1,000°C as well (see table p. 100).

According to a report of the Stuttgart City Building Administration, covering 48 cremations carried out between 20 July and 15 September 1909 in a Wilhelm Ruppmann Furnace, the briefly attained maximum temperature in the cremation chamber was 1,120°C (Nagel 1922, p. 37).

In the cremation experiments carried out by the engineer Richard Kessler at the Dessau Crematorium between 1 November 1926 and 12 January 1927 using a Beck Furnace (an improved version of the Klingenstierna Model), the highest temperature reached in the cremation chamber was 1,100°C, but this maximum was attained only for a few moments during the combustion of the coffin (cf. Document 48).

In the analysis proffered in Chapters 5f. of Unit I, I referred to various cremation charts for operation with coke, gas, and electricity which all show that the temperature of the muffle never reached a point above 1,100°C.

In the three charts known to me describing the operation of the electrical Topf Furnaces at Erfurt (Documents 142, 146 & 148) the highest temperature reached momentarily was around 1,120°C.

It is thus a fact that, in the furnaces for civilian use referred to by the Soviet experts, cremation-chamber temperatures higher than 1,100°C had not been established; effective temperatures of 1,500°C occurred only on the hearth grates (H. Keller 1929, p. 3).

It follows that the Soviet chart, to the extent that it covers temperatures higher than 1,000°C, is based on an inadmissible extrapolation. This is confirmed by the experiments carried out in England in the 1970s which I discussed in Chapter 6 of Unit I: in the chart illustrating the time-temperature relationship (Document 87), the temperature describes a wave-like curve: the minimum cremation time – 61 minutes – occurred at a temperature of 800°C; as the temperature rose up to 1,000°C, the time increased as well: 65 minutes at 900°C, and 67 minutes at 1,000°C. Then it started decreasing again, reaching 65.5 minutes at 1,100°C. At higher temperatures, unreached by experiments, Dr. Jones surmised that the duration should diminish further and should go below the thermal barrier at some threshold temperature. If one wanted to reduce the cremation time in this manner for example to 20 or 15 minutes, it would be necessary to design a furnace operating at around 2,000°C (see pp. 108f.).

The Soviet experts made another inadmissible extrapolation with respect to the furnace load. As the cremation of several corpses simultaneously in the same cremation chamber was prohibited for civilian cremations, no experimental data exist in this regard. Hence the Soviet chart necessarily rests on data for individual cremations. The Soviet experts therefore illicitly assign data valid for individual cremations to loads of two to twelve corpses in one muffle. Loading twelve corpses into one muffle is merely an arithmetical maneuver in order to artificially raise the furnaces' capacity. In this way, the three Stutthof Furnaces were attributed a capacity identical to the six furnaces at Sachsenhausen!

However, in the preceding section we have seen that increasing the load in a cremation chamber inevitably leads to a longer duration of the incineration and

that, for a furnace designed for individual cremations, this increase in time is such that no practical advantage can be gained from such a procedure.

The coke consumption purported by the Soviet experts – 60 kg for six emaciated corpses of 50 kg each – is mere conjecture without any technical basis. Let us recall the fact that in the Model 1b Kori Furnace, the incineration of 310 kg of organic substance – the equivalent of six corpses of some 51 kg each – necessitated, at steady-state conditions, a supply of some 130 kg of solid fuel, the equivalent of 140 kg of coke altogether, or 23 kg per corpse.

On the subject of the loading of corpses at the Lublin Crematorium, the Soviet experts really allow their imagination to run wild: the claim that, in front of the furnaces, they had found corpses without legs and without arms, "heavily damaged by fire" (*mnogo obgorebshich*), does not prove that the limbs of these corpses were cut off before being loaded into the furnace, it rather demonstrates that the last cremations were not carried out to the end, and when the carbonized corpses were later pulled out, they no longer had any arms or legs simply because the limbs burned faster than the trunks (as indeed they do).

The Soviet experts' assertions are technically untenable also with respect to the discharge gases and the cross-sectional area of the chimney at the Lublin crematorium.

First of all the experts misread Kori's letter of 8 January 1943.[537] The document merely states that the two forced-draft devices were necessary in order to be independent of weather conditions. The chimney draft was in fact affected by the fact that the exhaust gases cooled noticeably when they lost some of their heat in the two recuperator chambers for the purpose of preparing hot water for inmate showers. As a result of high outside temperatures during the summer months (the document says "especially on hot summer days"), the natural chimney draft could be reduced too much, which should be quite obvious.

The calculation of the cross-section of the two smoke ducts – the experts give only the result – is wrong, first of all because of the erroneous assumption that cremation proceeded with an excess-air ratio of 1.3. This is only half of what is actually needed. Furthermore, the result of the computation itself is wrong. As we can see from the Soviet experts' report on the furnaces at the Sachsenhausen Camp, the calculation of the chimney section carried out by the experts was based on the following formula (cf. page 43):

$$q = \frac{V\,(1 + \alpha t)}{3{,}600\ \text{sec/hr} \cdot v} \qquad [118]$$

where q = cross-sectional area of chimney
V = volume of off-gas in Nm^3 per hr
$\alpha = {}^{1}/_{273}\ °C^{-1}$
t = temperature of the off-gas in the chimney, °C
v = velocity of the off-gas in the chimney in m/sec.

Assuming a load of four corpses in each muffle, a duration of the cremation of 12 minutes, a generation of 285 m^3 off-gas per corpse, an off-gas temperature in the chimney of 400°C, and a gas velocity of 3 m/sec as assumed by the Soviets

[537] GARF, 7021-107-9, p. 250; Dokument published in Graf/Mattogno, p. 313.

(see p. 329), we obtain for the required cross-section of one chimney duct collecting the gases of 2.5 muffles (there were two ducts for five muffles):

$$S = \frac{285\ \text{Nm}^3/\text{hr} \cdot 4\ \text{corpses/muffle} \cdot 2.5\ \text{muffles/duct}\ (1 + \alpha \cdot 400°\text{C})}{3{,}600\ \text{sec/hr} \cdot 3\ \text{m/sec}} \cdot \frac{60\ \text{min/hr}}{12\ \text{min/corpse}}$$

$$= 3.25\ \text{m}^2. \qquad [119]$$

In other words, the calculated hourly generation of 35,100 m³ of off-gas would have required a cross-sectional area of 3.25 m² for each of the two chimney ducts, or nine times the actual dimension (with the actual cross-section, the gas velocity would have had to amount to 27 m/sec, or 60 mph – a true storm!). But in their computation the Soviet experts did not even consider the gas stemming from the combustion of the coke – as if the corpses underwent a process of auto-combustion!

In conclusion we may say that, as no cremation furnace actually operated at average temperatures higher than 1,000°C, and as any loading of several copses into one muffle would at least have multiplied the time taken in proportion to the number of corpses loaded, the chart produced by the Soviet experts is counter factual or totally afactual.

In fact, the Kori furnaces at Sachsenhausen, Majdanek and Stutthof, if we assume an average operating temperature of 800°C and a duration of 50 minutes for a single cremation (as in the Kori Furnaces at Westerbork), had cremation capacities of 144, 115, and 58 corpses in 24 hours, respectively.

This means that the Soviet experts, by using a technical sleight of hand, multiplied the actual cremation capacities by a factor of five for Sachsenhausen, a factor of thirteen for Majdanek, and a factor of ten for Stutthof! What should be stressed here, though, is that not even the Soviet experts ventured so far as to attribute to any actual cremation temperature a duration of less than 60 minutes for the cremation process: even to the highest temperature, 1100°C, occurring only for a few moments, they assigned a substantial duration of 75 minutes.

9.3.5. The Soviet and Polish Reports on the Topf Cremation Furnaces at Auschwitz-Birkenau

In February of 1945, the Soviet commission of inquiry investigating Auschwitz assigned the task of giving an expert opinion on the subject of the cremation furnaces at that camp to the engineers Dawidowski, Dolinskii, Lavrushin and Shuer. The experts, however, limited themselves to furnishing the following very-sparse data without any technical explanation:[538]

Crematorium I

– 3 to 5 corpses were loaded simultaneously into each muffle;
– cremation took 90 minutes;
– the number of corpses cremated amounted to 300 to 350 per day.

[538] "Akt 14 February – 8 March 1945. City of Oswiecim." GARF,7021-108-14, pp. 2-7.

Crematoria II/III

– 3 to 5 corpses were loaded together into each muffle;
– the cremation of which took 20 to 30 minutes;
– at full capacity, 6,000 corpses per day could be cremated in the 30 muffles of the two crematoria.

Crematoria IV/V

– 3 to 5 corpses were loaded into each muffle;
– the cremation took 30 to 40 minutes;
– at full capacity, 3,000 corpses per day could be cremated in the 16 furnaces of these crematoria.

On 26 September 1946, the engineer Roman Dawidowski, an expert witness with the court conducting the Rudolf Höss Trial, drew up a long opinion on the crematoria at Auschwitz-Birkenau.[539] Dawidowski was a mechanical engineer in the field of heat and combustion technology, but his opinion shows only a very rudimentary knowledge with respect to cremation furnaces. His documentation on the civilian crematoria in Germany consists of an excerpt of the "Law on Cremation" of 15 May 1934 (pp. 13-16) and of three drawings of cremation furnaces of the Siemens type (p. 16) – similar to those published here (Document 21) – as well as of the Didier (p. 17) and Gebrüder Beck Furnaces (p. 18), identical to those published here (Documents 59f.) and stemming from the same source.

On the subject of the Auschwitz-Birkenau Furnaces, Dawidowski merely reiterated the statements made in the report of the Soviet experts mentioned above without any further explanation:

Crematorium I

> *"The cremation of a load in 4 muffles took about one half-hour, therefore, in continuous operation over 14 hours per day, the cremation capacity of Crematorium I in its original state* [with two furnaces] *was more than 200 corpses per day.* […] *After this enlargement* [*i.e.*, after adding the third furnace]*, the cremation capacity of Crematorium I rose to some 350 corpses per day."* (pp. 24f.)

Crematoria II/III

> *"On average, five corpses were loaded into each muffle at one time. Cremation of such a load took 25-30 minutes. The 30 muffles of the two Crematoria II and III could cremate 350 corpses per hour. In the expert's opinion, for a continuous operation in two shifts of 12 hours per day and setting aside 3 hours of inactivity per day for the extraction of the slag from the gasifiers and for other minor work, with the unavoidable interruptions of continuous operation, the average number of corpses actually cremated in the two crematoria in 24 hours was 5,000 corpses. This figure agrees with the testimonies of the eye-witnesses Tauber and Jankowski."* (p. 47)

---

[539] AGK, NTN, 93, pp. 1-57; subsequent page numbers from there unless stated otherwise.

Crematoria IV/V

> *"In these crematoria, too, 3-5 corpses were loaded into each muffle. Cremation of such a load took about 30 minutes. In the expert's opinion, the two Crematoria IV and V, at full capacity with 2 shifts of 12 hours, considering stoppages for the removal of slag from the gasifiers, unforeseen incidents, bottle-necks etc., could cremate 3,000 corpses per day on average. This figure is in agreement with the depositions of eye-witnesses."* (p. 48)

In order to attain such performances – if we follow the Soviet chart discussed above – the furnaces at Crematorium I would have had to be operated at 1,000°C, those at Crematoria III and IV at more than 1,400°C, and those at Crematoria IV and V at more than 1,300°C. Yet only the first temperature mentioned is in any way feasible. As I have already stated, Topf's operating instructions for the triple-muffle furnaces recommended not to exceed a temperature of 1,000°C in the muffles. Even Dawidowski himself, during the fourteenth session of the Höss Trial, declared explicitly that[540]

> *"the cremation process for corpses is very difficult, requiring a precise temperature of 1,000°C; if the temperature is higher, the ash does not remain loose but attaches itself to the slag* [forming] *a compact mass. If the temperature is less than 1,000°C, the muscles will not burn…."*

A duration of the cremation process of 25 to 30 minutes is without any technical foundation as well, while the simultaneous cremation of three to five corpses in each muffle would at least have multiplied the duration of the process by a factor of 3 to 5.

Just like the Soviet expert opinions, Dawidowski's did not have a scientific character, but a political one, as it was to back up the wild exaggerations of the witnesses regarding the claimed aggregate number of cremations. The cremation capacities averred by the experts were not the result of an investigation, but of its afactual premises.

Summarizing our findings, we see that the practical performance of the double-muffle Topf Furnace at Gusen and of the Kori Furnace at Westerbork, the practical experience with the Kori Furnaces for the destruction of animal remains, the thermal load on the muffles, the calculation of the chimney cross section, as well as, indirectly, the findings of the Soviet and Polish experts concur to demonstrate that in the Topf Furnaces at Auschwitz-Birkenau a good and efficient cremation (with respect to time and fuel consumption) of several corpses in one muffle was technically impossible and any cremation of several corpses in one muffle would not have boosted the cremation performance of the furnaces in any way. As a matter of fact, it most-likely would have reduced the performance, in particular for more than two corpses per muffle.

9.3.6. The Presence of Child Corpses

For completeness's sake we must also consider the possibility that there were children and undersize adults among the corpses. The number of Jewish children and adolescents deported to Auschwitz has been estimated at about

[540] AGK, NTN, 111, p. 1572.

216,300 (Kubica 1999, p. 349) out of 1,095,000 deported (Piper 1993, p. 200), which amounts to 19.75%, or about one child among five deportees. The percentage, however, is calculated in relation to those presumed murdered – about 607,800 (Mattogno 2019, pp. 471f.) – and corresponds to about every third such deportee. The average weight of children up to the age of 16 is about 35 kg (Graf/Kues/Mattogno, pp. 138-141), so the average weight of two adults and one child is [(70+70+35)÷3=] 58 kg. In the Westerbork Crematorium the cremation of an adult corpse alone and that of an adult and a child corpse together lasted on average [(50+57)÷3=] 35 minutes per corpse. Considering, however, that an average cremation of an adult corpse lasted 60 minutes in the Topf Furnaces (not 50) and that the ages of the children ranged from one day to 16 years (and not merely from one day to one year), it is evident that the average cremation at Auschwitz lasted well over 35 minutes. Reasoning by analogy with the furnaces for the destruction of animal carcasses, we can assume that the simultaneous cremation of an average adult of 70 kg and an average child of 35 kg in one muffle lasted [(70+35) kg × (50 sec/kg ÷ 60 sec/min) =] 87.5 minutes, and that the average duration of the cremation of the bodies of two adults and one child lasted (175 kg × $^{5}/_{6}$ min/kg ≈) 146 minutes, or on average 48.6 minutes per corpse. This duration appears credible given the fact that, as mentioned earlier, in the Paris crematorium of Père-Lachaise the average duration of the cremation of the bodies of children up to 9 years was about 39 minutes. Therefore, the presence of children among the cremated corpses would have enhanced the capacity of the cremation furnaces only marginally by some 20%, yet even that would not even get close to the capacities claimed in the letter by the Central Construction Office of 28 June 1943 and in Prüfer's memo of 8 September 1942.

9.4. Maximum Theoretical Cremation Capacity

Our final task is to present the general conclusions concerning the performance of the Topf Furnaces at Auschwitz-Birkenau.

Assuming an average operating time of the furnaces of 20 hours per day and an average cremation time of 60 min per normal corpse, resulting in 20 cremations per day and muffle, the maximum cremation capacities of these devices were as follows:

Table 6: Maximum Daily Cremation Capacity*

Crematorium	# of muffles	# of cremations
I	6	120
II	15	300
III	15	300
IV	8	160
V	8	160
	Total	*1,040*

* assuming 1hr cremation time per corpse and 20hr/day operation

9.5. Normal Cremation Capacity

The cremation capacities as given in the preceding subchapter are purely theoretical, as they do not take into account one crucial element: according to the *Aktenvermerk* of 17 March 1943 (cf. Document 264), which will be analyzed in Chapter 10, the normal activity of the crematoria was set at 12 hours per day, which took into account the inevitable wear and tear of the equipment. The normal cremation capacities thus correspond to 60% of the above values, or:

Table 7: Normal Daily Cremation Capacity*

Crematorium	# of muffles	# of cremations
I	6	72
II	15	180
III	15	180
IV	8	96
V	8	96
I to V	*52*	*624*
II to V	*46*	*552*

* assuming 1hr cremation time per corpse and 12hr/day operation

The last row shows the total after deducting Crematorium I, which was replaced by the new Crematoria II to V.[541]

Was this an excessive capacity? To answer this question, we must go more deeply into the history and the function of the Birkenau Crematoria. The "new crematorium" with its five triple-muffle furnaces (the future Crematorium II) was designed for a camp with 125,000 Soviet prisoners of war. Thus, a detainee-to-muffle ratio of (125,000÷15 =) 8,333 was assumed. The explanatory report (*Erläuterungsbericht*) of 30 October 1941 set forth that each muffle was to cremate two corpses concurrently, thus enabling the cremation of 60 corpses in one hour or two corpses in one muffle every 30 minutes (see p. 266).

For a daily operating period of 12 hours, the daily cremation capacity would thus have been (60×12=) 720 corpses. Actually, though, as we have noted in Chapter 7, the type of triple-muffle furnace that was eventually built did not correspond to the technical characteristics of the devices considered in the file memo. Hence the capacity mentioned in the file memo did not correspond to the later reality, all the more so as even the cremation of a single corpse in one muffle within 30 minutes (on average) would have been technically impossible.

This observation, however, does not touch in any way on the intentions of the Auschwitz SS who, for a crematorium built without any criminal aim, counted on a normal cremation capacity of (720×30=) 21,600 deaths per month, or a mortality of (21,600÷125,000×100≈) 17.3% of the total camp strength per month. This high level of mortality had occurred in October of 1941.[542] The above computation is presented only as a concrete point of reference.

---

[541] In this context we also ought to consider the concept of reserve furnaces; for example, at the new Lublin Crematorium, the central furnace (one out of five) was specifically labelled "*Reserveofen*." Cf. Section 11.2.6. Assuming that every fifth furnace served as a reserve, this would further reduce the contemplated capacity to 552×0.8 = 442 corpses in 12 hours.

[542] Between 7 and 31 October 1941, 2,128 detainees died; the average strength for that month was

Obviously, as we shall see presently, the camp administration did not expect to see a loss as high as 21,600 detainees per month throughout the entire year; the camp headquarters – in line with the initial estimates – merely wanted to be able to cope with emergency situations of a daily mortality of up to 720 detainees for short periods of time.

The origins of the other three crematoria at Birkenau had two causes: the outbreak of a disastrous typhus epidemic, and the plans for the enlargement of the camp (see Mattogno 2010). The August of 1942 was the month during which the typhus epidemic took on horrifying proportions. This was also the month during which the decision was taken to build the other three crematoria.

In the course of the month, a total of 8,354 detainees (6,829 men and 1,525 women) died, 269 per day on average.[543] Over the first 19 days of the month of August, 4,113 deaths were registered in the men's camp alone. Between 10 and 19 August, 2,824 detainees would die, 282 per day on average, with daily maxima of 390 deaths on the 18th, 324 on the 13th, and 301 on the 11th.[544] Considering the fact that mortality was 49 per day in the women's camp, it is not overly adventurous to say that in August of 1942 the daily death rate exceeded 300 per day, with high points above 400 cases.

This catastrophic scenario unfolded at a time when high-flying plans for the Birkenau Camp were being mulled over. As early as June of 1942, the *WVHA* planned to raise the PoW camp strength to 150,000 detainees,[545] and in August this planning figure had reached 200,000 detainees.[546] Of course, the planned installation of appropriate hygienic and sanitary facilities as well as disinfestation plants would help to suppress another virulent outbreak of such an epidemic, but how could one be sure?

The decision to build more crematoria practically imposed itself, along with the choice of a sufficient number of muffles for the new installations, or in practical terms their cremation capacity. It was influenced by the two facts mentioned above: the excessive mortality among the detainees, and the plans for enlargement of the Birkenau Camp, which would have brought about an enormous increase in the number of inmates.

Available statistics allow us to say that in August 1942 the detainee mortality reached a level of 29.8% of the average camp strength in the men's camp (some 22,925 detainees), hitting highs of 37.9% of the average strength of 23,142 detainees between the 10th and the 19th of that month.[547]

If then – for the men's camp alone with an average strength of 23,000 inmates – there were 6,829 deaths equivalent to a momentary rate of 37.9% of the camp strength, what would or could happen with a camp strength of 150,000 or 200,000 detainees?

12,500 detainees, which yields a mortality rate of about 17%.

543 PRO, HW 1/929 xc 11768.

544 *Stärkebuch*, analysis by Jan Sehn. AGK, NTN 92, pp. 82f.

545 Radiomessage from Kammler to Bischoff dated 22 June 1942. GARF, 7021-108-32, p. 32.

546 Letter by Bischoff to Kammler dated 27 August 1942. GARF, 7021-108-32, p. 41.

547 *Stärkebuch*, analysis by Jan Sehn. AGK, NTN 92, pp. 82f.

At that level, the effective cremation capacity of 624 corpses per day (of 12 operating hours) or some 19,000 in one month would have corresponded to a mortality of 12.5% for a camp strength of 150,000 and no more than 9.4% for a strength of 200,000 detainees; in other words, only one third or one quarter, respectively, of the levels reached in August of 1942.

These considerations help us in understanding the problems which affected the SS's choice for a suitable capacity for the new crematoria. Fortunately, a Central Construction Office document of 10 July 1942 furnishes us with the criteria of that decision: On 15 June 1942, the Construction Office of the Stutthof Camp sent a request to the Central Construction Office at Auschwitz regarding information concerning the installation of a crematorium. On 10 July, Bischoff answered with the following letter (Document 263):[548]

> *"In the attachment, we are sending you the plans for a crematorium for 30,000 detainees. The plant consists of 5 triple-muffle cremation furnaces. According to information supplied by Topf & Söhne Co. of Erfurt, a cremation takes about one half-hour.*
> *The basement has been raised because the ground-water level at the construction site is high. Concerning technical installation, we refer you to Topf & Söhne Co. of Erfurt."*

The duration of half an hour for one cremation was nothing but an extrapolation on Topf's part, because at that moment no triple-muffle furnace had yet been built. What is important in this letter, however, is the ratio of muffles to detainees established by the Central Construction Office, viz. (30,000÷15=) one muffle for 2,000 detainees.

This clearly shows that the Central Construction Office did, in fact, not trust the data of the explanatory note of 30 October 1941 (which Topf had provided), because on the basis of such data, and assuming an operation of 12 hours per day, the crematorium would have been able to handle (720×30=) 21,600 corpses per month or [(21,600÷30,000)×100] = 72% of the camp strength for which it was designed.

In practical terms, the Central Construction Office approved an enormous reduction of the new crematorium's capacity when it set the effective cremation capacity to be sufficient no longer for 125,000 inmates, as stated in the explanatory report, but rather for 30,000 inmates, or at (30,000÷125,000×100=) 24%; *i.e.* in numerical terms, at (720×0.24≈) 173 cremations per day.

On the basis of the ratio of muffles to detainees set by the Central Construction Office, the 46 muffles of the four crematoria at Birkenau were sufficient for (46×2,000=) 92,000 detainees. This computation by the Central Construction Office formed the basis for the later decision to build the other three crematoria and constituted the criterion for the choice of the number of muffles.

The increase of the camp strength to a level of 200,000 detainees was mere conjecture and turned out to be increasingly illusory over the following months. The layout of the PoW camp of 15 August 1942 (Pressac 1989, p. 203), though based on a population of 200,000 detainees, showed only two crematoria (the

[548] Letter from Bischoff to *Bauleitung* of Stutthof dated 10 July 1942. RGVA, 502-1-272, p. 168.

future Crematoria II and III), or a ratio of muffles to detainees of (30÷200,000=) 1:6,666. The drawing of 22 September 1942 (*ibid.*, p. 209), still showing merely the two crematoria just mentioned, was elaborated for a strength of only 140,000 detainees or a ratio of (140,000÷30=) one muffle for 4,667 detainees.

The final drawing of 6 October 1942,[549] including all four crematoria for an unchanged camp strength of 140,000 detainees, yielded a new ratio of (140,000÷46=) 1 muffle for 3,043 detainees. Taking into account the slow progress of the construction of the camp, the strength of 140,000 remained purely theoretical;[550] it was reached only as late as August 1944 under the enormous overload caused by the deported Hungarian Jews.[551]

Considering the fact that the projected strength for the Birkenau Camp stood at 140,000 detainees and the normal strength of the Auschwitz Camp amounted to 10,010 in November of 1942,[552] *i.e.* a total of 150,000 detainees, we may say, based on the Central Construction Office calculations, that the crematoria eventually installed were most inadequate for the aimed-at increase of the camp strength, which would indeed have necessitated (150,000÷2,000=) 75 muffles as compared to the 46 eventually built.

The conclusion of the matters discussed above is that the Birkenau Crematoria were conceived only on the basis of registered detainees, without any criminal intentions, and were to allow for possible future emergency situations with considerable peaks in mortality, in line with the experience gathered in August of 1942. They reflected an effective cremation capacity of only 50% of the theoretical, and thus an effective average operating time of 12 hours per day.

Although the projected strength of the Birkenau Camp was 140,000, the four crematoria – which were really designed for a strength of only 92,000 – were not used to full capacity for two reasons: first of all, the actual strength stood nearly always below this limit.[553] Secondly, the actual construction of the camp with all the projected sanitary, hygienic, and medical installations, led to a considerable drop in mortality. After the 1942 typhus epidemic, such a drop occurred as early as April of 1943, and over that year the mortality dropped steadily, reaching a low of 2.3% in October 1942 (Langbein 1965, vol. 1, pp. 100f.).

9.6. Discussion of the *Zentralbauleitung* Letter of 28 June 1943

At the end of the preceding subchapter, we left in suspension the technical examination of the cremation capacity as indicated in the Central Construction Office letter of 28 June 1943. Now, having ruled out – in terms of economy and duration – the efficient simultaneous cremation of multiple corpses in one muffle in the Auschwitz-Birkenau Furnaces, we can state with certainty that such a capacity is technically impossible.

---

549 VHA, OT 31(2)/8.

550 It is known that *Bauabschnitt* III was never finished.

551 According to information gathered by the Polish resistance movement, the camp strength of the Auschwitz-Birkenau Camp was 135,168 detainees in August of 1944 (Czech 1989, p. 860).

552 "*Normale Block-Belegstärke im K.L.Auschwitz*." 3 November 1942. RGVA, 502-1-272, p.56.

553 In 1943, the maximum camp strength was 88,251 detainees (1st December). *Übersicht über den Häftlingseinsatz im K.L. Auschwitz. Dezember 1943*. APMO, D-AuI-3a/370, pp. 438, 448.

This judgment is strengthened further by the fact that, as we shall see in Chapter 10, the minimum theoretical fuel requirement of a Topf triple-muffle or 8-muffle furnace for the type of corpse which demanded the lowest amount of fuel was 16 and 12 kg of coke per corpse, respectively. In view of the fact that the furnaces of Crematoria II and III of Birkenau could burn (35 kg/hr/hearth · 2 hearths/furnace · 5 furnaces · 24 hr =) 8,400 kg of coke in 24 hours and those of Crematoria IV and V (35 kg/hr/hearth · 4 hearths/furnace · 24 hr =) 3,360 kg, if the Crematoria II and III did in fact have a capacity of 1,440 corpses in 24 hours, the average coke consumption per corpse would have been a mere (8,400÷1,440=) 5.83 kg; for Crematoria IV and V, a capacity of 768 corpses in 24 hours would have meant an average consumption of only (3,360÷768=) 4.37 kg of coke, but such figures would be only about one third of the minimum theoretical requirements.

The capacity indicated in the letter of 28 June 1943 is, therefore, technically impossible to attain. How can we explain this dilemma?

Jean-Claude Pressac has shown correctly (1989, p. 244) that the cremation capacity given in the document, as far as Crematoria II-V are concerned, is closely linked arithmetically to the capacity mentioned in the previously mentioned explanatory report of 30 October 1941 (Document 211), *i.e.* two corpses in one half-hour in one muffle or four corpses per hour per muffle, which match precisely the numbers in the letter:

$4 \times 15 \times 24 = 1{,}440$ corpses in 24 hours in Crematoria II-III
$4 \times 8 \times 24 = 768$ corpses in 24 hours in Crematoria IV-V

However, there is no direct relationship between the five triple-muffle furnaces mentioned in that report and the furnaces that would eventually be installed in Crematoria II and III at Birkenau. In October of 1941, the triple-muffle Topf Furnace was still on the drawing boards, and the only determined basic design fact was that it would consist of three muffles which were linked in one way or another. The reference which appears in the explanatory report of 30 October 1941 therefore concerned an elusive project in Kurt Prüfer's mind, different from what was later realized, in the same way as the project described in the "quotation for the delivery of two triple-muffle cremation furnaces" of 12 February 1942 (Document 228), in which the triple-muffle furnace still had a single gasifier situated behind the center muffle.

The link between the projected cremation capacity of the triple-muffle furnaces in the explanatory report of 30 October 1941 and the letter of 28 June 1943 was thus purely formal. But what was the basis for such a link? The document in question allows us to formulate a plausible answer. The document, in fact, betrays certain anomalies, the most-important of which are the presence of a bureaucratic element which should not be there and the absence of one which should be there.

The letter of 28 June 1943 refers to the "completion of Crematorium III." A report about the completion of a construction site (or building) was an official document sent to the *WVHA* in compliance with a specific order by Kammler of

6 April 1943.[554] What was required in this case was the notification of the completion of a construction project and a report about the respective hand-over negotiation (*Übergabeverhandlung*).

For this reason, the "list of construction projects already handed over to the camp administration,"[555] drawn up by Bischoff in accordance with Kammler's directives, contains, *i.a.*, the registration number of the letter by which the hand-over negotiation for the four Birkenau Crematoria had been reported to the camp commandant of the Auschwitz Camp, and the handover date and registration number of the letter of notification to the head of Office Group C at the *WVHA*.

Now, even though the report about the hand-over negotiation of Crematorium III was drawn up on 24 June 1943[556] and passed on to the *Kommandantur* probably on the same day[557] and even though the garrison administration had taken over Crematorium III officially on 25 June,[558] the letter of 28 June does not address this state of the matter at all, and that is what should be there but is not.

The notification of completion was a purely formal act simply conveying the fact that a construction project had been finished, but it never gave any technical details of the project, which means that the listing of cremation capacities in the letter of 28 June 1943 makes no sense, bureaucratically speaking, and this is the element which should not be there.

What is even odder is the fact that this notification of completion is only about Crematorium III, but the letter mentions the cremation capacity of *all* crematoria. One would have to surmise that Bischoff must have been requested explicitly the supply of such information to Kammler. But in that case, bureaucratic practice would have required that he reply by a specific letter mentioning, in the line *Bezug* (reference) the registration number and the date of Kammler's letter. Instead, the letter of 28 June 1943 merely states *Bezug: ohne* (reference: none).

The letter shows two more anomalies. First of all, the use of the word *Personen* (persons) as the cremation units. This term is somewhat odd, as one would rather expect the term "corpses" (*Leichen*) or at least "detainees" (*Häftlinge*). Furthermore, in the letter in question, the cremation capacity is given for a continuous operation of 24 hours per day, but – as we have explained in Subchapter 9.1. – this was not feasible with coke-fired furnaces. It is not by accident that the file memo of 17 March 1943 has a "daily operation" of 12 hours.

It is highly unlikely that Bischoff, in a formal official document, would have made so many gross mistakes.

Another strange thing worth noting is that the letter in question is a unique document, unrelated to others: no other document exists which mentions or in

[554] Letter from Kammler "to all building inspectorates and building sections" (*an sämtliche Bauinspektionen und Baugruppen*) dated 6 April 1943. WAPL, *Zentralbauleitung*, 54, p. 68.
[555] APMO, 30/25, p. 14.
[556] RGVA, 502-2-54, p. 84.
[557] Bischoff's letter of transmittal erroneously has the date of 23 June 1943. RGVA, 502-2-54, p. 21.
[558] APMO, 30/25, p. 14.

any way refers to the cremation capacities claimed in it. The matter is even more mysterious, as it is an official document addressed to the Head of Office Group C of the *WVHA*, *SS Brigadeführer und Generalmajor der Waffen-SS* Kammler. Office C/III handled technical matters and encompassed four main departments, among which we have one for civil engineering (C/III/1) and one for mechanical and electrical engineering (C/III/3) which also included a subsection for heating and ventilation (C/III/3a).[559]

Since the cremation capacities mentioned in this letter were technically impossible, how can we believe that the engineers of Office C/III, in the face of such obviously erroneous statements, would not have asked Bischoff for more information? Bischoff would have had to answer, and a correspondence would have ensued of which there is, however, not the slightest trace.

The most-obvious conclusion we may draw from the remarks made above is that the author of this letter was completely unfamiliar with the technical question of the capacity of the cremation furnaces, and not very familiar with the bureaucratic practices in place here either, something which certainly does not apply to Bischoff and makes us rather think of someone from another branch of the Central Construction Office[560] and with a still-limited knowledge of the procedures followed in this office, possibly *SS Sturmmann* Nestripke, whose initials appear in the registration number of the document.

The author of the letter, being inexperienced, left out the data required for a report about the hand-over transaction, and added to the notification of completion, on his own initiative, the unrequired data about the crematoria's capacity, based on the explanatory report of 30 October 1941, because he might have thought that for bureaucratic reasons – as Pressac has pointed out – the furnace capacities had to correspond to the 1941 explanatory report.[561] In that case, we would not be dealing with an intentional "exaggeration", a bragging about unattainable performances (as Pressac believed), but with a simple case of incompetence within bureaucratic procedures.

That this might be true is demonstrated by Bischoff's letter to the Construction Office of the Stutthof Camp of 10 July 1942, which we have discussed earlier. It is obvious that Bischoff could not reasonably have recommended an installation with an actual capacity of 1,440 corpses in 24 hours for a camp with a mere 30,000 detainees, because this would have corresponded to a capacity of (1,440×30=) 43,200 corpses per month, *i.e.* 13,200 more than the number of detainees concerned.

Hence, Bischoff would have been fully aware of the erroneous character of the cremation capacity given in the letter of 28 June 1943, which is yet another confirmation of the utter strangeness of this document.

We have yet to look at one more point: was the letter of 28 June 1943 ever sent to the *WVHA*? As we have already pointed out, this would have undoubted-

---

[559] RGVA, 502-1-4, p. 28.

[560] In January of 1943, the *Zentralbauleitung* at Auschwitz comprised 14 departments (*Sachgebiete*) and was divided into 5 *Bauleitungen*. Cf. C. Mattogno 2015.

[561] However, the cremation capacity attributed to Crematorium I had no relationship either with the above document or with reality and it is very difficult to say where the figure came from.

ly led to an exchange of letters, of which there is neither a trace in the Central Construction Office archives nor in the records of the Pohl Trial (Pohl was the head of the *WVHA*).

The fact that the letter bears no signature could mean that Bischoff, noticing the double error it contained, refused to sign it and had it retyped in a corrected version mentioning the hand-over transaction and omitting the capacity of the furnaces. There are instances of documents thrown out and retyped correctly with the registration number unchanged, for example the file memo of 13 September 1943, of which we have one version full of mistakes corrected by hand[562] and a retyped and corrected version signed by Kirschnek and Bischoff.[563] The fact that no copy of the corrected version of the document discussed here exists in the Moscow Central Construction Office archives may of course have been caused by the selection of the documents as practiced by the Soviets. The fact that the archives of the Central Construction Office, kept partly in Moscow and partly in Auschwitz, do not contain any drawings of the Topf Crematoria is undoubtedly due to this selection process.

9.7. The Durability of Refractory Lining

Due to the thermal stresses to which it is subjected, the refractory lining of a cremation furnace undergoes inevitable wear and tear that seriously compromises the efficiency of the plant eventually.

In an article published on 25 October 1941, engineer Rudolf Jakobskötter described the third electric furnace at the Erfurt Crematorium and noted in this context (1941, p. 583):

> *"Since over 3000 cremations have been performed in the second electric furnace in Erfurt, while the muffles had previously only withstood about 2000 cremations, depending on their design, it can be claimed that the design has fully proven itself in terms of durability. The manufacturing company expects a service life of 4000 cremations per muffle in the future."*

In the municipal crematorium of Erfurt, three electric furnaces had been built in succession. The first (1934-1935) had performed 1,294 cremations, after which it was dismantled; after 2,910 cremations conducted between 1936 and 1939, this second furnace was replaced by the third furnace, which performed 1,417 cremations in the period from 1940 to April 1941 (*ibid.*, p. 586). The 3,000 cremations mentioned above referred (with some exaggeration) to the second furnace, the 4,000 cremations were an expectation relegated to the future, perhaps connected to the third furnace, while the 2,000 cremations concerned the coke and gas furnaces.

For the furnaces at the concentration camps, the problem of wear and tear on the refractory lining was more serious, both because of the lower mass and the low quality of the refractory lining, and because of the greater stress on the equipment – both due to mechanical stress and also because the inmate staff was certainly not motivated to run the furnaces with great care.

---

[562] APMO, BW 30/25, pp. 11f.
[563] RGVA, 502-1-26, pp. 144-146.

How real the effect of these factors was is demonstrated by the case of the Topf double-muffle furnace at the Gusen Camp. This furnace was commissioned on 29 January 1941,[564] but after only eight months, it was already seriously damaged. On 24 September of 1941, the Mauthausen Construction Office asked Topf to send a technician to repair the furnace immediately.[565] Topf sent the technician August Willing, the same man who had built the device. Willing arrived at Gusen on 11 October 1941 and started work the next day. The receipts for the work show that the work was carried out from 12 October to 9 November 1941. In the week of 16 to 22 October, he replaced the refractory lining of the furnace in 68 hours of work. The following week, during 68 hours of work, he completed the reconstruction of the outer brick sheathing of the furnace and performed a test cremation. Willing remained in Gusen until 9 November to fine-tune the furnace and supervise its operation.[566]

From 1 February to 15 October 1941, the day on which the last cremations were carried out before the furnace was shut down for repairs, hence within 260 days, 2,876 inmates had died and had been cremated at the Gusen Camp, in addition to about 14 more inmates between 29 and 31 January, hence a total of 2,890 inmates. Therefore, 1,445 cremations had been carried out in each muffle (Marsalek 1980, p. 156).

This confirms that the average duration of the refractory lining of a muffle was of the order of magnitude of 2,000 cremations. The attainment of 3,000 cremations mentioned above referred to the second electric furnace in Erfurt. However, an electric furnace, because of the uniform distribution of the heat it provided, had a longer life span than coke-fired furnaces, because its refractory lining was subjected to less thermal stress. Therefore, this figure is not applicable to coke-fired furnaces.

Replacing the entire refractory linings of the cremation muffles at the Auschwiz crematoria would have required an enormous amount of material and labor, inevitably producing a large number of documents, but there is no trace of any such documents in the voluminous correspondence between the Topf Company and the Central Construction Office of the Auschwitz Camp. The extant documents do not even contain passing hints or references to them. More-crucially, such a massive replacement project is not part of the activities carried out by the Topf Company at Auschwitz-Birkenau, which we were able to reconstruct completely thanks to the complete set of invoices.

From these documents, as I mentioned earlier, it appears that only one railway car of refractory material was sent to Auschwitz as replacement material: on 9 December 1941, the Central Construction Office had ordered a rail-car load of refractory material "as spare materials for repair work." They were used for the repair of the second furnace at the crematorium in the Auschwitz Main Camp. Taking into consideration this single replacement of the refractory ma-

[564] Data taken from the list of coke deliveries to the Gusen Crematorium. ÖDMM. B 12/31, p. 352.

[565] Letter of the SS *Bauleitung* of the Mauthausen Camp to Topf of 24 September 1941. BAK, NS 4 Ma/54.

[566] J.A. Topf & Söhne, "*Bescheinigung über besondere Berechnung geleistete Tagelohn-Arbeiten*" by the SS *Bauleitung* of the Gusen Camp, 12 October to 9 November 1941. BAK, NS 4/Ma 54.

sonry of two muffles, the furnaces of this crematorium could have cremated a maximum of (2,000 × 6 + 2 × 2,000 =) 16,000 corpses. Therefore, the total number of corpses that could have been cremated in the furnaces at Auschwitz and Birkenau together was approximately (46 × 2,000 + 16,000 =) 108,000 corpses.

For a more-detailled discussion of this topic, I refer the reader to a separate study (Rudolf/Mattogno 2017, pp. 144-150).

9.8. The Effective Equivalent Operating Time of the Birkenau Cremation Furnaces

Due to the Topf Furnaces' oversimplified and in-part-flawed design – with their refractory masonry being too light and their lack of regulating devices for the individual muffles – they constantly experienced breakdowns and had damaged components in need of repair, which frequently interrupted their activity, sometimes even for long periods, as we have documented in Chapter 6 of Unit II. We summarize here the relevant data with the necessary explanations.

In 1943, Crematorium II operated at reduced capacity at least from 9 April to 16 May, hence for at least 38 days. In view of the caution that the damage to the old chimney of Crematorium I (which had to be demolished and rebuilt) must have inspired in the Central Construction Office, for this period we can assume a 50% operation time (= 10 hours per day), which is equivalent to a shut-down time of 19 days. From 17 May to 31 August, hence for 107 days, this crematorium was completely closed for major repairs.

The inactivity of individual furnaces of Crematoria II and III in connection with the repair of the furnace doors or closures, considering that a triple-muffle furnace had ten doors and/or closures and that twenty were being repaired for 294 days and seven of them for 30 days, which is equivalent to ten doors and/or closures for about 600 days, and considering that there were ten furnaces in these crematoria, this all corresponds to about 60 more days of inactivity for these two crematoria.

On 2 February 1944, damage to the refractory masonry of "furnaces" (plural) of Crematoria II and III was discovered, which was repaired after 22 February. Therefore, the damage concerned at least two furnaces (in each of the two crematoria), which remained idle for at least 25 days, which is equivalent to a shut-down time of (1 × 25/5 =) five days of activity for each crematorium.

Rudolf Höss stated after the war that Crematorium IV "failed completely after a short time and later ceased to be used altogether" (Höss 1959, p. 143). Although various documents mention repairs made to this crematorium, there is in fact no documentary evidence that it was in operation in the second half of 1943 and in 1944.

At the beginning of May of 1944, damage to the refractory masonry of the smoke ducts or chimneys of Crematoria II, III and IV was discovered. In the absence of reference points, we can assign a minimum time of three days for the repair work for each crematorium.

Altogether, therefore, Crematoria II and III were idle for at least (60 + 5 + 5 + 3 + 3 =) 76 days in 1944, an average of 38 days per crematorium; Crematorium IV for at least 3 days.

From the available documents, the following picture of the activity and inactivity of the crematoria at Birkenau emerges:

1943	TIMEPERIOD	EXISTENCE	ACTIVE	INACTIVE
Crematorium II	14 March – 31 December	293 days	167 days	126 days
Crematorium III	25 June – 31 December	190 days	190 days	/
Crematorium IV	22 March – 31 December	285 days	50 days	235 days
Crematorium V	4 April – 24 June	272 days	82 days	190 days
TOTAL:		1,040 days	489 days	551 days

1944	TIME PERIOD	EXISTENCE	ACTIVE	INACTIVE
Crematorium II	1 January – 30 October	304 days	266 days	38 days
Crematorium III	1 January – 30 October	304 days	266 days	38 days
Crematorium IV	–	–	–	–
Crematorium V	1 January - 30 October	304 days	144 days	160 days
TOTAL:		912 days	676 days	236 days

These two tables do not take into account the days of inactivity caused by the failures of individual furnaces as mentioned in Chapter 6. The duration of activity considered here stops in 1944 on 30 October because at that time the alleged murderous function of the crematoria is said to have ceased.

The total number of days the crematoria at Birkenau were in operation can now be calculated:

Crematorium	Total Days in Service
Crematorium II Crematorium III	889
Crematorium IV Crematorium V	276

However, these figures are a purely theoretical maximum, because it is not known for how many days which and how many furnaces were actually in operation. It should also be mentioned that, according to a note by civilian employee Jährling dated 17 March 1943 on the "Estimation of coke consumption at Crematorium II, *KGL*, based on data received from the Topf & Söhne Co. (builders of the furnaces) on 11 March 1943," the daily service time of the crematoria was calculated only for 12 hours.

9.9. The Auschwitz-Birkenau Crematoria in the General Operation of the Camp

In the preceding section we investigated the question of the design and construction of the Birkenau crematoria. To round out our treatment, we have yet to look into the importance which the camp administration attributed to them.

The documents tell us not only that the Auschwitz-Birkenau Crematoria never played a major role in the history of the camp, but that they did not even

enjoy the same degree of attention which the Central Construction Office devoted to a much more prosaic combustion plant: the local heating plant (*Fernheizwerk*), *BW* 161. We will limit ourselves to a few significant aspects.

On 27 June 1942, Friedrich Boos, the contractor for this installation, informed the Central Construction Office that the firm Walther & Co. Dampfkesselwerk at Cologne, which he had contacted, required the following data for an offer concerning the steam boilers it manufactured:[567]

1. type of fuel
2. moisture content of the fuel
3. ash content of the fuel
4. volatiles in the fuel
5. granularity of the fuel
6. melting point of the slag from the fuel
7. softening point of the slag
8. analysis of the feed water.

The installation required 45 to 50 tons of coal daily!

As the district heating plant was to use hard coal from Upper Silesia, the Central Construction Office forwarded the questions to the Mining and Metallurgical Association of Upper Silesia,[568] and received the following information:[569]

	Lump coal, Types III/IV	Ground coal
Size	10/20 mm, 20/30 mm	0 – 10 mm
Humidity	8 – 12%	10 – 14%
ash	7 – 10%	10 – 15%
volatiles	35 – 40%	33 – 38%
Ash melting point: in general 1,200 to 1,300°C.		

To assess the suitability of various types of coal, specific combustion experiments were carried out.[570] For the district heating plant, four "Holland" type boilers were to be installed with a heating-surface area of 150 m² and a total consumption of hard coal of about 400 to 500 kg/hr, depending on size,[571] but probably only three boilers were eventually installed, because on 13 October 1944 the Central Construction Office ordered from Friedrich Boos "3 pcs. suction and fly-ash-removal devices" for three "Holland boilers" with a heating surface of 150 m² at a price of 21,909.50 RM each.[572] The chimney to which

[572] Letter from F. Boos to *Zentralbauleitung* dated 27 October 1944. RGVA, 502-1-138, p. 5.

these devices were to be connected had a height of 22.2 m and three ducts 0.70 by 0.70 m each.[573]

Boos's proposal for the forced-draft devices took into account all pertinent physical data. For the *Saugzuganlage Type H 13* serving a boiler of 150m² heating surface, the proposal specified:[574]

– volumetric flow rate of the gases:	13,000 m³/hr or 3.75 m³/sec
– gas temperature:	310°C
– density of the gas:	0.62 kg/m³
– static pressure at blower exit:	40 mm water column
– margin of 10% as requested:	4 mm water column
– margin for flow resistance:	55 mm water column
– difference in static pressure:	99 mm water column
– power requirement for blower:	10 hp
– speed of blower:	1,435 rpm

In the documentation concerning the Birkenau Crematoria there is no instance of comparable diligence.

10. Heat Balance of the Topf Furnaces at Auschwitz-Birkenau

10.1. Remarks on the Method Used

In Subchapter 8.3 we analyzed the list of cremations carried out in the crematorium at the Gusen Concentration Camp, which possessed a coal-fired Topf double-muffle furnace. Among other things, this list contains the consumption of coke for each cycle of cremations. This allows us to calculate the average coke consumption for each corpse. As these consumptions represent data obtained under actual conditions of operation, they constitute a valuable point of departure for the calculation of the overall heat balance of the Topf Furnaces at Auschwitz-Birkenau.

These data will be used to arrive at reliable results, to the greatest extent possible, by means of the method employed by engineer Heepke as described in Chapter 7 of Unit I, but with the considerable advantage – in the case of the Gusen Furnaces – that we know in advance what the actual result of the heat balance should be. Without this knowledge, such a heat balance might be in agreement with furnaces for civilian use, but not for those erected in the concentration camps, whose main feature was their greater economy as compared to the civilian furnaces, both in terms of price and fuel economy.

The Topf Furnace at Gusen was similar in design to the Topf double-muffle furnace at Auschwitz, although it had structural differences which had a certain

---

[573] *Zentralbauleitung*, *Kosten-Berechnung über den Neubau eines Schornsteines* (cost estimate for the new construction of a chimney) for BW 161. 1943. RGVA, 502-1-139, p. 7.

[574] Letter from F. Boos to *Zentralbauleitung* dated 24 May 1943. RGVA, 502-1-138, pp. 218-218a.

bearing on the heat balance: due to a different structure of the muffle grate and the availability of a draft enhancer which brought about a higher heat availability, the Gusen Furnace's average duration of a cremation was around 40 minutes; thus, the average temperature of this furnace was higher than that of the Auschwitz-Birkenau Furnaces, for which we have calculated an average duration of 60 minutes for the cremation of one normal corpse.

The operating temperature of the Auschwitz furnaces being 800°C, as imposed by the applicable operating instructions and in line with civilian furnaces, we may assume an average temperature of 850°C for the Gusen Furnace. Since we have no operational data about the off-gas temperature of the Auschwitz-Birkenau Furnaces, we must use the highest values encountered in civilian furnaces, because the furnaces in the concentration camps had no recuperators and would thus necessarily have had a higher off-gas temperature than civilian furnaces.

Operational data for the Berlin Gerichtsstraße Crematorium tell us that it operated with an off-gas temperature of 700°C at the flue-gas damper, with an excess-air ratio three times the volume of the theoretical combustion air (Tilly 1926b, p. 190). The four gas-fired Volckmann-Ludwig Furnaces, built in 1932 by the H.R. Heinicke Co. at the Hamburg-Ohlsdorf Crematorium, functioned with an average temperature of 800 to 900°C; the flue-gas temperature, measured directly behind the damper, was normally 100°C lower (Manskopf 1933, p. 775). These furnaces did not have a recuperator, which means that the flue-gas discharge was comparable to the Topf Furnaces at Auschwitz-Birkenau.

Consistent with these documents, one may also assign to the Topf Furnaces an off-gas temperature some 100°C lower than that of the furnace itself, hence 750°C for the Gusen Furnace and 700°C for the furnaces at Auschwitz-Birkenau.[575]

For comparison, we also present two other series of coke-consumption figures obtained during actual operation, meaning those for the Kori Furnace at Westerbork (Subchapter 8.4) and the Kori Furnaces for slaughterhouses already analyzed in Section 9.2.1.

10.2. Technical Data

Following German contemporary literature, we will subsequently use the abbreviations used in the pertinent literature for the following physical properties:

V_{sch} = *Verlust durch Schornstein*, chimney losses (sensible heat of the flue gases; see Eq. 65, p. 120)

V_a = *Verlust durch Asche*, ash losses (incombustibles of the hearth; see Eq. 75, p. 121)

V_{un} = *Verlust Unverbranntes*, losses due to unburnt gases (see Eq. 74, p. 120)

R_g = *Rauchgasgewicht*, weight of discharge gases (see Eq. 69, p. 120)

[575] The irreparable damage to the chimney of Crematorium I and to the flue ducts of Crematorium II (cf. Chapter 6) confirm the high flue-gas temperatures. The replacement of the refractory lining of the chimney's inner walls was carried out when the temperature of the smoke exceeded 500°C (Colombo 1926, p. 400). The new chimney for Crematorium I was lined with bricks having a Seger value of 26/28, which withstood temperatures up to 1,200-1,300°C (RGVA, 502-1-318, p. 1).

η = *Wirkungsgrad*, efficiency
ηH_u = *Wirkungsgrad, unterer Heizwert*, lower heating value as a function of efficiency (see Eq. 83, p. 122)
V_{ls} = *Verlust durch Leitung/Strahlung*, loss through conduction and radiation (see Eq. 81, p. 121)

10.2.1. Basic Data on Coke

a. The chemical composition of the coke most-likely used was:[576]

C	78.84%
H	0.51%
O	1.00%
S	0.91%
water	8.21%
ash	10.53%
	100.00%

b. Theoretical combustion air (see Eq. 3, p. 25):

$$8.93 \times 0.7884 + 26.79 \times (0.0051 - 0.01/8) + 3.35 \times 0.0091 = 7.17 \text{ m}^3/\text{kg} \quad [120]$$

c. Theoretical smoke volume (dry, see Eq. 7, p. 25):

$$8.93 \times 0.7884 + 21.17 \times (0.0051 - 0.01/8) + 3.35 \times 0.0091 = 7.15 \text{ m}^3/\text{kg} \quad [121]$$

d. CO_2 content (see Eq. 21, p. 31):

$$0.7884 \times 1.867 = 1.472 \text{ m}^3/\text{kg};\ 1.472 \times 100 \div 7.17 = 20.50\% \quad [122]$$

e. Lower heating value (see Eq. 1, p. 24):

$$8{,}100 \times 0.7884 + 28{,}700 \times (0.0051 - 0.01/8) + 2{,}210 \times 0.0091 - 600 \times 0.0821$$
$$\approx 6{,}470 \text{ kcal/kg.} \quad [123]$$

10.2.2. Basic Furnace Data

1. Auschwitz Double-Muffle Furnace

Dimensions

– surface area: 32 m²
– surface area of gasifiers: 7 m²
– surface area of furnace body: 25 m²
– weight of refractory brickwork: 10,000 kg
– average brickwork composition:

	thickness [cm]	λ (800°)
refractory bricks:	15	0.73
thermal insulation:	7	0.13
ordinary bricks:	20	0.45
total:	42	–

with λ = thermal conductivity [kcal m^{-1} $°C^{-1}$ hr^{-1}]

[576] According to the chemical analysis given by Heepke; cf. Unit I, Chapter 7.

– average smoke temperature: 700°C
– load: 2 corpses
– average duration of a cremation: 60 min
– heat loss by radiation and conduction:

Doors	**Dimensions [m]**	**Surface area [m²]**
2 vaulted muffle doors (*Einführungstüren*)	0.60 × 0.60	0.64[577]
2 hearth doors (*Feuertüren*)	0.28 × 0.35	0.20
2 ash-chamber doors (*Ascheentnahmetüren*)	0.28 × 0.35	0.20
2 gasifier closures (*Generatorfüllschachtverschlüsse*)	0.27 × 0.34	0.18
6 combustion-air-channel closures (*Luftkanalverschlüsse*), four in furnace body, two in gasifier	0.108 × 0.126	0.08
total surface area		1.30
Muffle doors		
thickness	0.10	
packing mass thickness (*Stampfmasse*)	0.08	
packing mass surface area		~ 0.32 m²
surface area of solid metal		~ 0.32 m²
surface area of frames (solid metal)		~ 0.23 m²
total surface area of solid metal		~ 0.55 m²

Muffle-Door Losses

Following Eq. 54 (p. 117) and using a thermal conductivity of 40 kcal m^{-1} $°C^{-1}$ hr^{-1} for the 0.02 m of cast iron, we calculate the thermal transmittance K for the muffle doors:

$$K = \frac{1}{\frac{1}{7} + \frac{0.08}{0.73} + \frac{0.02}{40} + \frac{1}{7}} \approx 2.6 \text{ kcal m}^{-2} \text{ °C}^{-1} \text{ hr}^{-1} \quad [124]$$

Other-Door Losses (hearths, ash chambers and gasifiers)

– total thickness: 0.080 m
– thickness of packing mass: 0.065 m
– thickness of cast iron: 0.150 m
– total surface area: 0.580 m²

$$K = \frac{1}{\frac{1}{7} + \frac{0.065}{0.73} + \frac{0.015}{40} + \frac{1}{7}} \approx 2.7 \text{ kcal m}^{-2} \text{ °C}^{-1} \text{ hr}^{-1} \quad [125]$$

Brickwork Losses

$$K = \frac{1}{\frac{1}{7} + \frac{0.15}{0.73} + \frac{0.07}{0.13} + \frac{0.20}{0.45} + \frac{1}{7}} \approx 0.68 \text{ kcal m}^{-2} \text{ °C}^{-1} \text{ hr}^{-1} \quad [126]$$

[577] The upper half of the doors was a semi-circle, hence: 0.6 m × 0.3 m + π × 0.3² m²/2 = 0.321 m² each.

Losses by Conduction and Radiation (V_{ls})

i) Furnace body:
   a) Muffle doors:
      V_{ls} (tamping mass) = 0.32 m² · 2.6 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C)
      = 649 kcal/hr
      V_{ls} (solid metal) = 0.55 m² · 40 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C)
      = 17,160 kcal/hr
   b) Ash-chamber doors:
      V_{ls} = 0.20 m² · 2.7 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C) = 421 kcal/hr
   c) Combustion-air-channel closures:
      V_{ls} = 4 · (0.108 m · 0.126 m) · 40 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C)
      = 1,698 kcal/hr
   d) Brickwork (surface area of furnace body minus aggregate door surface a) to c)):
      V_{ls} = (25 – 1.1) m² · 0.68 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C)
      = 12,677 kcal/hr

ii) Gasifiers:
   a) Doors (hearths and gasifiers):
      V_{ls} = 0.38 m² · 2.7 kcal m^{-2} °C^{-1} hr^{-1} · (1000°C – 20°C) = 1,005 kcal/hr
   b) Combustion-air-channel closures:
      V_{ls} = 2 · (0.108 m · 0.126 m) · 40 kcal m^{-2} °C^{-1} hr^{-1} · (1000°C – 20°C)
      = 1,066 kcal/hr
   c) Brickwork (surface area of gasifiers minus doors a) & b)):
      V_{ls} = (7 – 0.39) m² · 0.68 kcal m^{-2} °C^{-1} hr^{-1} · (1000°C – 20°C)
      = 4,405 kcal/hr

iii) Total losses:

649+17,160+421+1,698+12,677+1,005+1,066+4,405 ≈ 39,000 kcal/hr [127]

2. Gusen Double-Muffle Furnace

– surface area: 28 m²
– surface area of gasifiers: 16 m²
– surface area of furnace body: 12 m²

Losses by Conduction and Radiation (V_{ls})

i) Furnace body:
   a) Muffle doors:
      V_{ls} (caulking mass) = 0.32 m² · 2.6 kcal m^{-2} °C^{-1} hr^{-1} · (850°C – 20°C)
      = 690 kcal/hr
      V_{ls} (solid metal) = 0.55 m² · 40 kcal m^{-2} °C^{-1} hr^{-1} · (850°C – 20°C)
      = 18,260 kcal/hr
   b) Ash-chamber doors:
      V_{ls} = 0.20 m² · 2.7 kcal m^{-2} °C^{-1} hr^{-1} · (850°C – 20°C) = 448 kcal/hr
   c) Combustion-air-channel closures:
      V_{ls} = 0.054 m² · 40 kcal m^{-2} °C^{-1} hr^{-1} · (850°C – 20°C) = 1,793 kcal/hr

d) Brickwork:
V_{ls} = (12–1.1) m² · 0.68 kcal m^{-2} °C^{-1} hr^{-1} · (850°C–20°C) = 6,152 kcal/hr

ii) Gasifiers:

a) Doors (of hearths and gasifiers):
V_{ls} = 0.38 m² · 2.7 kcal m^{-2} °C^{-1} hr^{-1} · (1,150°C – 20°C) = 1,159 kcal/hr

b) Combustion-air-channel closures:
V_{ls} = 0.027 m² · 40 kcal m^{-2} °C^{-1} hr^{-1} · (1,150°C – 20°C) = 1,220 kcal/hr

c) Brickwork:
V_{ls} = (16–0.4) m² · 0.68 kcal m^{-2} °C^{-1} hr^{-1} · (1,150°C–20°C) = 11,987 kcal/hr

iii) Total losses:

690+18,260+448+1,793+6,152+1,159+1,220+11,987 ≈ 41,709 kcal/hr [128]

3. Auschwitz Triple-Muffle Furnace

Dimensions

– surface area: 43 m²
– surface area of gasifiers: 10 m²
– surface area of furnace body: 33 m²
– weight of refractory brickwork: 11,500 kg
– average brickwork composition:

	thickness [cm]	λ (800°)
refractory bricks:	15	0.73
thermal insulation:	7	0.13
ordinary bricks:	20	0.45
total:	42	

with λ = thermal conductivity [kcal m^{-1} °C^{-1} hr^{-1}]

– average off-gas temperature: 700°C
– load: 3 corpses
– average duration of cremation: 60 min
– heat loss by radiation and conduction:

Doors	**Dimensions [m]**	**Surface area [m²]**
3 muffle doors (*Einführungstüren*)	0.65 × 0.65	1.13[578]
2 hearth doors (*Feuertüren*)	0.28 × 0.35	0.20
3 ash-chamber doors (*Ascheentnahmetüren*)	0.28 × 0.35	0.30
2 gasifier-feed-shaft closures (*Generatorfüllschachtverschlüsse*)	0.27 × 0.34	0.18
8 combustion-air-channel closures (*Luftkanalverschlüsse*)	0.108 × 0.126	0.11
total surface area		1.92

[578] The upper half of the doors was a semi-circle: 0.65 m × 0.325 m + π × 0.325² m²/2 = 0.377 m² each.

Muffle Doors		
thickness	0.10	
packing mass thickness (*Stampfmasse*)	0.08	
caulking mass surface area		≈ 0.565
surface area of solid metal		≈ 0.565
surface area of frames		≈ 0.460
total surface area of solid metal		≈ 1.025

Door and Brickwork Losses

Due to identity in their features, these coefficients are the same as for the Auschwitz Topf double-muffle furnaces (see there).

Losses by Conduction and Radiation (V_{ls})

i) Furnace body:
   a) Muffle doors:
      V_{ls} (packing mass) = 0.565 m² · 2.6 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C)
      = 1,146 kcal/hr
      V_{ls} (solid metal) = 1.025 m² · 40 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C)
      = 31,980 kcal/hr
   b) Ash-chamber doors:
      V_{ls} = 0.30 m² · 2.7 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C) = 631 kcal/hr
   c) Combustion-air-channel closures:
      V_{ls} = 0.08 · 40 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C) = 2,496 kcal/hr
   d) Brickwork:
      V_{ls} = (33 – 2.1) m² · 0.68 kcal m^{-2} °C^{-1} hr^{-1} · (800°C – 20°C)
      = 16,389 kcal/hr

ii) Gasifiers:
   a) Doors (hearths and gasifiers):
      V_{ls} = 0.38 m² · 2.7 kcal m^{-2} °C^{-1} hr^{-1} · (1000°C – 20°C) = 1,005 kcal/hr
   b) Combustion-air-channel closures:
      V_{ls} = 0.03 · 40 kcal m^{-2} °C^{-1} hr^{-1} · (1000°C – 20°C) = 1,176 kcal/hr
   c) Brickwork, identical with double-muffle furnace:
      V_{ls} = (10 – 0.4) m² · 0.68 kcal m^{-2} °C^{-1} hr^{-1} · (1000°C – 20°C)
      = 6,397 kcal/hr

iii) Total losses:

1,146+31,980+631+2,496+16,389+1,005+1,176+6,397

≈ 61,220 kcal/hr [129]

Heat loss from the center muffle:

i) Furnace body:
   a) Muffle door: one door, of three total, hence a third of the total value:

$$V_{ls}\text{ (muffle door)} = \frac{1{,}146\text{ kcal/hr} + 31{,}980\text{ kcal/hr}}{3} = 11{,}042\text{ kcal/hr}$$

b) Ash-chamber doors: one of three total, hence a third as well:

$$V_{ls} \text{ (ash door)} = \frac{631 \text{ kcal/hr}}{3} \approx 210 \text{ kcal/hr}$$

c) Combustion-air-channel closures: two out of a total of eight:

$$V_{ls} \text{ (air channel lids)} = \frac{2{,}496 \text{ kcal/hr} \cdot 2}{8} \approx 624 \text{ kcal/hr}$$

d) Brickwork: roughly 8 m² out of a total of 30.9 m²:

$$V_{ls} \text{ (brickwork)} = \frac{16{,}389 \text{ kcal/hr} \cdot 8}{30.9} \approx 4{,}243 \text{ kcal/hr}$$

iii) Total losses:

$$(11{,}042 + 210 + 624 + 4{,}243) \text{ kcal/hr} \approx 16{,}120 \text{ kcal/hr} \quad [130]$$

Heat loss from both lateral muffles:

$$61{,}220 \text{ kcal/hr} - 16{,}120 \text{ kcal/hr} \approx 45{,}100 \text{ kcal/hr} \quad [131]$$

10.2.3. Basic Data on Corpses

1. Normal Corpse

Weight: 70 kg; chemical composition (cf. Unit I, Subchapter 1.2.):

Compound	Weight	Proteins	Fats
C	13.2846 kg	6.6402 kg	6.6444 kg
H	1.8060 kg	0.8694 kg	0.9366 kg
O	3.8178 kg	2.9988 kg	0.8190 kg
S	0.1512 kg	0.1512 kg	0.0000 kg
N	1.9404 kg	1.9404 kg	0.0000 kg
water	45.5000 kg		
ash	3.5000 kg		
Total:	*70.0000 kg*	*12.6000 kg*	*8.4000 kg*

Using the pertinent equation as indicated, we obtain the following values:

QUANTITY	VALUE	EQUATION
theoretical combustion air:	155 m³	3, p. 25
theoretical dry-smoke volume:	149 m³	7, p. 25
theoretical moist-smoke volume:	226 m³	11, p. 26
water vapor:	77 m³	9, p. 26
upper heating value:	146,100 kcal	105, p. 126

2. Lean Corpse

The influence of the combustibility of a corpse on the amount of fuel required for a cremation (as well as on its duration) has been demonstrated repeatedly. An important observation was made by the engineer Hans Keller, who said (cf. Unit I, Subchapter 5.3.):

> *"Corpses burning easily will initially produce up to 16%, even 17% of CO_2; with corpses that are difficult to burn, this value goes down to 4%."*

Experimental data collected in Germany in the 1930s show that 65% of all corpses burned normally, 25% poorly and 10% burned with difficulty (Jakobskötter 1941, p. 587). Speaking of the electric furnace at Biel in Switzerland, H. Keller says in this connection (H. Keller 1935c, p. 3):

> *"The great majority by far* [of the corpses] *will burn within two hours for an initial temperature of 700°C. Cases for which the cremation is complete within an hour and a half are very rare. A little more common are cases in which the corpse does not burn easily and cremation requires up to five hours."*

The bodies of registered detainees who died in the concentration camps, in Auschwitz-Birkenau in particular, belonged to the category of corpses which burned poorly or with difficulty, because the highest mortality struck detainees whose bodies had been diminished by epidemics, hunger or deprivation. Extreme cases of this nature were described as "*Muselmänner*" [Moslems] in the camp jargon. For our purposes, we will assume a corpse of this type, with a weight loss of 30 kg – from 70 kg down to 40 kg[579] – and a proportional loss of its proteins of 50% (3.5 kg) and 60% of its body fat (1.8 kg), as compared to a normal corpse, which means that it would have had the following composition:

Chemical composition:

Water:	31.2 kg
Proteins:	3.5 kg
Fat:	1.8 kg
Incombustibles (Ash):	3.5 kg
Total:	40.0 kg

The combustible portions of the corpse are (3.5 + 1.8 =) 5.3 kg and have the following chemical composition:

$C = 3.5 \cdot 0.527 + 1.8 \cdot 0.7910 =$	3.27 kg
$H = 3.5 \cdot 0.069 + 1.8 \cdot 0.1115 =$	0.44 kg
$O = 3.5 \cdot 0.238 + 1.8 \cdot 0.0975 =$	1.01 kg
$N = 3.5 \cdot 0.154 =$	0.54 kg
$S = 3.5 \cdot 0.012 =$	0.04 kg
Total	5.30 kg

The upper heating value of the combustible substances amounts to (see the caloric values for fat and protein in Eq. 16, p. 29):

$$\text{u.h.v.} = 3.5\ \text{kg} \cdot 5{,}422\ \text{kcal/kg} + 1.8\ \text{kg} \cdot 9{,}257\ \text{kcal/kg} \approx 35{,}600\ \text{kcal} \qquad [132]$$

The theoretical volume of combustion air is (see Eq. 3, p. 25):

$$8.93 \cdot 3.27 + 26.77 \cdot (0.44 - 1.01/8) + 3.35 \cdot 0.04 = 38\ \text{m}^3 \qquad [133]$$

[579] A weight loss of 35-40% is normally fatal (McPhee/Papadakis/Tierney 2008, p. 1085). Here, we are looking at a lethal weight-loss as high as 42.8%.

3. Average Corpse

For the sake of completeness, we will also consider an intermediate case between the two extremes of a normal and an emaciated corpse, *i.e.* a corpse with a loss of 25% of its proteins and 30% of its fats as compared to a normal corpse. This would thus have the following composition:

Water:	39.6 kg
Proteins:	7.3 kg
Fat:	4.6 kg
Incombustibles (Ash):	3.5 kg
Total:	55.0 kg

This amounts to a loss of 15 kg or half the weight loss assigned to an emaciated body.

The combustible substances of such a body amount to 11.9 kg, with the following chemical composition:

$C = 7.3 \cdot 0.527 + 4.6 \cdot 0.7910 =$	7.49 kg
$H = 7.3 \cdot 0.069 + 4.6 \cdot 0.1115 =$	1.01 kg
$O = 7.3 \cdot 0.238 + 4.6 \cdot 0.0975 =$	2.19 kg
$N = 7.3 \cdot 0.154 =$	1.12 kg
$S = 7.3 \cdot 0.012 =$	0.09 kg
Total	11.90 kg

The upper heating value is:

$$\text{u.h.v.} = 7.3 \cdot 5{,}422 + 4.6 \cdot 9{,}257 \approx 82{,}200 \text{ kcal} \qquad [134]$$

The theoretical amount of combustion air is (Eq. 3, p. 25):

$$8.93 \cdot 7.49 + 26.77\,(1.01 - 2.19/8) + 3.35 \cdot 0.09 \approx 87 \text{ m}^3 \qquad [135]$$

10.3. Heat Balance of the Double-Muffle Furnace at Gusen

A total of 677 corpses were burned at the Gusen Crematorium with an average specific consumption of 30.6 kg of coke per corpse. I summarize the results of these operations in the following table for the 13 pertinent cremation series:

Table 8: Coke Consumption of the Gusen Crematory

CREMATION SERIES	START OF SERIES	TOTAL COKE CONSUMPTION	CORPSES	KG COKE PER CORPSE
1	31/10/1941	2,100 kg	63	33.3 kg
2	01/11/1941	1,260 kg	38	33.1 kg
3	02/11/1941	1,260 kg	42	30.0 kg
4	03/11/1941	1,140 kg	42	27.1 kg
5	04/11/1941	1,380 kg	49	28.1 kg
6	05/11/1941	1,320 kg	45	29.3 kg
7	06/11/1941	2,040 kg	57	35.7 kg
8	07/11/1941	2,700 kg	94	28.7 kg
9	08/11/1941	2,100 kg	72	29.1 kg
10	09/11/1941	1,140 kg	34	33.5 kg
11	10/11/1941	840 kg	30	28.0 kg
12	11/11/1941	1,920 kg	58	33.1 kg
13	12/11/1941	1,500 kg	53	28.3 kg
Total	–	*20,700 kg*	*677*	*30.6 kg*

Subsequently the heat balance is calculated for the three types of corpses mentioned before. I use the following abbreviation for the respective quantities:

– W = *Wärme*, heat.
– W_2 = heat of vaporization of the corpse water and its heating up to flue gas temperature (750°C; see Eq. 95, p. 124[580]).
– W_{2a} = heat required for heating up to flue-gas temperature the water vapor formed by combustion of the hydrogen contained in the dry substance of the body. Equation as before, but here a factor of 9 is applied because water (18 g/mol) has nine times the mass of the hydrogen contained in it (2 g/mol).
– W_3 = heat used for heating of ash to operating temperature (850°C; see Eq. 50, p. 117).
– W_7 = upper heating value of the corpse, explained in each instance below.

Physical units are given only for the first case, thereafter omitted for brevity's sake.

Two Lean Corpses:

W_2: $2 \cdot 31.2\ \text{kg} \cdot [633\ \text{kcal kg}^{-1} + 0.50\ \text{kcal kg}^{-1}\ °\text{C}^{-1} \cdot (750°\text{C} - 100°\text{C})] =$ 59,779 kcal
W_{2a}: $2 \cdot 0.44\ \text{kg} \cdot 9 \cdot 0.50\ \text{kcal kg}^{-1}\ °\text{C}^{-1} \cdot (750°\text{C} - 100°\text{C}) =$ 2,574 kcal
W_3: $2 \cdot 0.2\ \text{kcal kg}^{-1}\ °\text{C}^{-1} \cdot 3.5\ \text{kg} \cdot (850°\text{C} - 20°\text{C}) =$ 1,162 kcal
W_7 (see Eq. 132, p. 361): 71,200 kcal

[580] The average heat capacity of steam between 100°C and 750°C is roughly 0.50 kcal $\text{kg}^{-1}\ °\text{C}^{-1}$, see www.engineeringtoolbox.com/water-vapor-d_979.html.

Two Average Corpses:

W_2: $2 \cdot 39.6 \cdot [633 + 0.5 \cdot (750 – 100)] =$	75,874 kcal
W_{2a}: $2 \cdot 1.01 \cdot 9 \cdot 0.5 \cdot (750 – 100) =$	5,909 kcal
W_3: $2 \cdot 0.2 \cdot 3.5 \cdot (850 – 20) =$	1,162 kcal
W_7 (see Eq. 134, p. 362):	164,400 kcal

Two Normal Corpses:

W_2: $2 \cdot 45.5 \cdot [633 + 0.5 \cdot (750 – 100)] =$	87,178 kcal
W_{2a}: $2 \cdot 1.806 \cdot 9 \cdot 0.5 \cdot (750 – 100) =$	10,565 kcal
W_3: $2 \cdot 0.2 \cdot 3.5 \cdot (850 – 20) =$	1,162 kcal
W_7 (see Eq. 105, p. 126):	292,200 kcal

Heat Losses from the Furnace:

I have here used the abbreviations and equations as indicated at the beginning of Subchapter 10.2.

$$V_{sch} = \left(0.32 \cdot \frac{78.84}{0.536 \cdot 13.7} + 0.0048 \cdot (9 \cdot 0.51 + 8.21)\right) \cdot (750–20) \cdot \frac{100}{6{,}470}$$

$$\approx 39.4\%$$

$$V_a = 49.5 \cdot \frac{2.8 \cdot 8{,}100}{61 \cdot 6{,}470} \approx 2.8\%$$

$$R_g = \frac{0.01 \cdot 78.84}{0.536 \cdot \frac{13.7 + 0.5 + 0.3}{100}} \approx 10.1 \text{ kg}$$

$$V_{un} = \frac{10.1\ (3{,}050 \cdot 0.5 + 2{,}580 \cdot 0.4)}{6{,}470} \approx 4\%$$

This results in an efficiency of:

$$\eta = 100 – (39.4 + 2.8 + 4) = 53.8\%$$

and thus an effective lower heating value of coke of:

$$\eta H_u = 6{,}470 \cdot 0.538 \approx 3{,}480 \text{ kcal/kg}$$

Heat Balance for an Average Corpse

As the average consumption of the furnace is known (30.6 kg per corpse, or 61.2 kg for two of them), we will develop the heat balance as an equation in which the unknown stands for the heat needed to heat the combustion air for the corpse and to compensate for the other heat losses not treated by Heepke which, so far, we had not taken into account because they have no effect on the heat balance as such, but only on the volume of the combustion air and hence on that of the off-gas:

$$30.6 \text{ kg} \cdot 2 \cdot 3{,}480 \text{ kcal/kg} \approx 213{,}000 \text{ kcal} \qquad [136]$$

$$x + W_2 + W_{2a} + W_3 + V_{ls} - W_7 = 213{,}000 \text{ kcal} \quad [137]$$

$$x + 75{,}874 + 5{,}909 + 1{,}162 + 27{,}806^{581} - 164{,}400 = 213{,}000 \text{ kcal}$$

$$x = 266{,}649 \text{ kcal}$$

And hence, vice-versa, the heat balance for one average corpse is as follows:

$$\frac{x + W_2 + W_{2a} + W_3 + V_{ls} - W_7}{2 \cdot \eta H_u} =$$

$$\frac{266{,}649 + 75{,}874 + 5{,}909 + 1{,}162 + 27{,}806 - 164{,}400}{2 \cdot 3{,}480} = 30.6 \text{ kg of coke} \quad [138]$$

10.4. Heat Balance of the Double-Muffle Furnace at Auschwitz

10.4.1. Heat Losses for the Corpses

Two Lean Corpses

W_2: $2 \cdot 31.2 \cdot [633 + 0.49 \cdot (700 - 100)] =$	57,845 kcal
W_{2a}: $2 \cdot 0.44 \cdot 9 \cdot 0.49 \cdot (700 - 100) =$	2,328 kcal
W_3: $2 \cdot 0.2 \cdot 3.5 \cdot (800 - 20) =$	1,092 kcal
W_7:	71,200 kcal

Two Average Corpses

W_2: $2 \cdot 39.6 \cdot [633 + 0.49 \cdot (700 - 100)] =$	73,418 kcal
W_{2a}: $2 \cdot 1.01 \cdot 9 \cdot 0.49 \cdot (700 - 100) =$	5,345 kcal
W_3: $2 \cdot 0.2 \cdot 3.5 \cdot (800 - 20) =$	1,092 kcal
W_7:	164,400 kcal

Two Normal Corpses

W_2: $2 \cdot 45.5 \cdot [633 + 0.49 \cdot (700 - 100)] =$	84,357 kcal
W_{2a}: $2 \cdot 1.806 \cdot 9 \cdot 0.49 \cdot (700 - 100) =$	9,557 kcal
W_3: $2 \cdot 0.2 \cdot 3.5 \cdot (800 - 20) =$	1,092 kcal
W_7:	292,200 kcal

10.4.2. Heat Losses from the Furnace

$$V_{sch} = \left(0.32 \cdot \frac{78.84}{0.536 \cdot 13.7} + 0.0048 \cdot (9 \cdot 0.51 + 8.21)\right) \cdot (700 - 20)] \cdot \frac{100}{6{,}470}$$

$$\approx 36.7\%$$

$$V_a = 49.5 \cdot \frac{2.8 \cdot 8{,}100}{56 \cdot 6{,}470} \approx 3.1\%$$

$$V_{un} = 4\%$$

---

[581] The total heat loss by radiation and conduction over 40 minutes is: 41,709 kcal/hr × (40min÷60min/hr) = 27,806 kcal; see Eq. 128. p. 358.

$$\eta = 100 - (36.7 + 3.1 + 4) = 56.2\%$$

$$\eta H_u = 0.562 \cdot 6{,}470 \approx 3{,}640 \text{ kcal/kg}$$

Heat Balance for an Average Corpse

For the double-muffle furnace at Auschwitz, the heat loss associated with the combustion air of the corpses is lower than that for the Gusen Furnace, because for Auschwitz we have assumed a somewhat lower exhaust-gas temperature of 700°C, thus resulting in an energy requirement of:[582]

$$\frac{266{,}649 \cdot 0.328 \cdot (700 - 20)}{0.329 \cdot (750 - 20)} \approx 247{,}630 \text{ kcal} \qquad [139]$$

This corresponds to the heat needed for some 1,123 m³ of air to be brought to a temperature of 700°C. The coke required for the cremation of an average corpse is therefore:

$$\frac{x + W_2 + W_{2a} + W_3 + V_{ls} - W_7}{2 \cdot \eta H_u} =$$

$$\frac{247{,}630 + 73{,}418 + 5{,}345 + 1{,}092 + 39{,}000^{583} - 164{,}400}{2 \cdot 3{,}640} \approx 27.8 \text{ kg} \qquad [140]$$

Heat Balance for Lean and Normal Corpses

Before we proceed to lean and normal corpses, some further remarks on the Gusen cremation statistics are due.

In Table 8, I have list the cremations in the Gusen crematory with their respective coke consumption. Listing the same data sorted by increasing average coke consumption per corpses yields the following table:

Table 9: Ranked Gusen Coke Consumption for Cremations

coke/corpse [kg]	no. of corpses	coke/corpse [kg]	no. of corpses
27.1	42	30.0	42
28.0	30	33.1	38
28.1	49	33.1	58
28.3	53	33.3	63
28.7	94	33.5	34
29.1	72	35.7	57
29.3	45		

The differences in consumption are too large to be attributable simply to the furnace itself. They are no doubt due to differences in the types of corpses cremated. This is confirmed by the observation that the amount of coke used per corpse is not inversely correlated to the number of cremations, as one would expect. For example, on 3 Nov.[584] we have 42 cremations with an average consumption of 27.1 kg of coke per corpse, yet on the next day we have, for a total

[582] The factors 0.328/0.329 are a minute correction for the changed heat capacity of the exhaust gases at the lower temperature per Recknagel-Sprenge, p. 47.

[583] See Eq. 127, p. 357, assuming a cremation took an hour, see Subchapter 8.5.

[584] For reasons of convenience, I use the date corresponding to the beginning of the series.

of 49 cremations (seven more than the day before), an *increase* to 28.1 kilograms. The following day, the average consumption for 45 cremations rose still further to 29.3 kg, and hit a maximum value of 35.7 kg on 6 Nov. for 57 corpses. On 8 Nov., after 94 cremations, consumption rose from 28.7 to 29.1 kg, and on 9 Nov., after 72 cremations, it rose again from 29.1 to 33.5 kg; the minimum consumption of 27.1 kg was obtained on 3 Nov., with 42 cremations performed after the equally 42 cremations of the previous day, and the maximum value of 35.7 kg occurred on 6 Nov., with 57 cremations performed after the 45 cremations of the previous day. On 10 Nov., we have 33.5 kg/corpse for 34 corpses, yet the following day (11 Nov.), the average coke consumption *sank* to 28 kg, although the number of cremations also went down to 30. The next day (12 Nov.) saw a drastic increase in coke consumption per corpse to 33.1 kg in spite of an almost doubling of the number of cremations from 30 to 58.

If the higher consumption, compared to the general average, depended essentially on the furnace (accumulation of heat in the refractory masonry), more cremations would correspond to lower consumption, but the opposite happens at times in the cases mentioned above.

These differences in the specific consumption cannot be attributed to the handling of the furnace either, because up to 9 November the cremations were carried out under the supervision of Topf Technician August Willing.[585] Thus, a higher or lower consumption depends essentially on the type of corpse predominantly cremated.

The average coke consumption as a function of the type of corpse cremated can be split into two main groups:

– Between 27.1 and 30.0 kg: 427 corpses, or 63%
– Between 33.1 and 35.7 kg: 250 corpses, or 37%

It is easy to see that one may attribute to the first group primarily the corpses of an average to normal type, while those of an average to lean type would fall into the second category.

On a weighted-average basis, the former group has an average consumption of 28.6 kg of coke per corpse, the latter of 33.8 kg. The consumption of coke for the average corpse thus becomes [(33.8 + 28.6): 2=] 31.2 kg, essentially the same figure as the average specific consumption of 30.6 kilograms.

On the basis of these data, one can calculate the heat balance for each one of these groups to a fair degree of accuracy:

Heat Balance of the First Group (Normal to Average Corpses)

$$28.6\ \text{kg} \cdot 2 \cdot 3{,}480\ \text{kcal/kg} \approx 199{,}100\ \text{kcal} \qquad [141]$$

$$x + W_2 + W_{2a} + W_3 + V_{ls} - W_7 = 199{,}100\ \text{kcal}$$

Using the data as listed on p. 364 we obtain:

$$x + 87{,}178 + 10{,}565 + 1{,}162 + 27{,}806 - 292{,}200 = 199{,}100\ \text{kcal} \qquad [142]$$

[585] Topf, "*Bescheinigung über besondere Berechnung geleisteter Tagelohn-Arbeiten für Bauleitung der Waffen-SS und Polizei Gusen*," 12 October – 9 November 1941. BAK, NS 4/Ma 54.

$$x = 364{,}589 \text{ kcal}$$

This results in an energy requirement of:

$$\frac{364{,}589 \cdot 0.328 \cdot (700 - 20)}{0.329 \cdot (750 - 20)} \approx 338{,}600 \text{ kcal} \quad [143]$$

and by using the values for the Auschwitz furnace (p. 365) thus a coke requirement of:

$$\frac{338{,}600 + 84{,}357 + 9{,}557 + 1{,}092 + 39{,}000 - 292{,}200}{2 \cdot 3{,}640} \approx 24.8 \text{ kg} \quad [144]$$

Heat Balance of the Second Group (Average-to-Lean Corpses)

$$33.8 \text{ kg} \cdot 2 \cdot 3{,}480 \text{ kcal/kg} \approx 235{,}200 \text{ kcal} \quad [145]$$

$$x + 59{,}779 + 2{,}574 + 1{,}162 + 27{,}806 - 71{,}200 = 235{,}200 \quad [146]$$

$$x = 215{,}079$$

$$\frac{215{,}079 \cdot 0.328 \cdot (700 - 20)}{0.329 \cdot (750 - 20)} \approx 199{,}740 \text{ kcal} \quad [147]$$

and thus a coke requirement of:

$$\frac{199{,}740 + 57{,}845 + 2{,}328 + 1{,}092 + 39{,}000 - 71{,}200}{2 \cdot 3{,}640} \approx 31.4 \text{ kg} \quad [148]$$

As the two groups comprise average-to-normal and lean-to-average corpses respectively, coke consumption for one normal corpse is somewhat less than 24.8 kg, and that of a lean corpse somewhat higher than 31.4 kilograms.

In the Kori Furnaces for the destruction of animal remains, lowest consumption was 0.268 kg of *hard coal* for 1 kg of organic substance, thus the minimum *coke* consumption for a normal corpse should be:

$$\frac{70 \text{ kg} \cdot 0.268 \text{ kg coal/kg} \cdot 7{,}500 \text{ kcal/kg hard coal}}{6{,}470 \text{ kcal/kg coke}} = 21.7 \text{ kg} \quad [149]$$

We may therefore assume the average value of about [(24.8 + 21.7) ÷ 2 =] 23.3 kg of coke for one normal corpse. Consumption of coke for the cremation of one lean corpse is thus [27.8 + (27.8 – 23.3) =] 32.3 kg, because the value for an average corpse is 27.8 kg and that of a normal corpse is 23.3 kilograms per corpse.

Based on these values, the heat balance is as follows:

Heat Balance for a Normal Corpse:

The energy stemming from the fuel is:

$$23.3 \text{ kg} \cdot 2 \cdot 3{,}640 \text{ kcal/kg} \approx 169{,}600 \text{ kcal} \quad [150]$$

The total energy requirement x is hence:

$$x + 84{,}357 + 9{,}557 + 1{,}092 + 39{,}000 - 292{,}200 = 169{,}600 \text{ kcal} \quad [151]$$

$x \approx 327{,}800$ kcal

Heat Balance for a Lean Corpse:

Again, the energy stemming from the fuel is:

$$32.3 \text{ kg} \cdot 2 \cdot 3{,}640 \text{ kcal/kg} \approx 235{,}150 \text{ kcal} \quad [152]$$

and hence the total energy requirement x:

$$x + 57{,}845 + 2{,}328 + 1{,}092 + 39{,}000 - 71{,}200 = 235{,}150 \text{ kcal} \quad [153]$$

$x \approx 206{,}100$ kcal

Summarizing, then, we have the following coke consumptions for the Auschwitz type Topf double-muffle furnace:

Table 10: Coke Consumption of the Auschwitz Double-Muffle Furnaces

TYPE OF CORPSE	COKE/CORPSE
Normal	23.3 kg
Average	27.8 kg
Lean	32.3 kg

10.5. Remarks on the Heat Balance

If the heat loss covered by the unknown "x" were entirely assignable to the combustion air, the following values would be valid for the three cases under consideration:

Table 11: Combustion-Air Requirement for the Cremation of Various Types of Corpses

CORPSE	x [kcal]	TOTAL AIR[586]	THEORETICAL AIR VOLUME[587]	EXCESS-AIR FACTOR
Normal	327,800	1,970 Nm³	644 Nm³	3.06
Average	247,630	1,708 Nm³	572 Nm³	2.99
Lean	206,100	1,627 Nm³	540 Nm³	3.01

As we can see, the excess-air ratio would be the same as for civilian crematoria, which appears too high; actually, there are heat losses not taken into account by Heepke in his calculation but which are here included together with the combustion-air losses:

1. heat loss due to incombustibles of the corpse;

---

[586] Equation used for normal corpses, e.g.: [327,800 kcal/0.328kcal°C^{-1}m^{-3} (700°C – 20°C)] + 23.3 kg · 2[corpses] · 1. 5[Excess-Air Coefficient, see p. 116] · 7.17 Nm³/kg ≈ 1,970 m³.

[587] Total theoretical air volume = volume needed for the corpse + volume needed for the fuel (coke); for corpse: Eq. 3, p. 25, with corpse data from Section 10.2.3, resulting in: 155 Nm³ (normal), 87 Nm³ (average) and 38 Nm³ (lean) (see Section 10.2.3).
For coke: Eq. 120, p. 355 (A_{tv} = 7.17 Nm³/kg), with coke consumption following Table 10, resulting in: 167 Nm³ (normal), 199 Nm³ (average) and 232 Nm³ (lean).
Hence for two muffles/corpses in the double-muffle furnace: normal: 2 (155+167) Nm³ = 644 Nm³; average: 2 (87+199) Nm³ = 572 Nm³; lean: 2 (38+232) = 540 Nm³

2. heat loss due to heating of the dry matter of the corpse up to muffle temperature;
3. heat loss due to heating of coke up to its ignition temperature;
4. heat loss due to the muffle heat absorbed by the corpse introduction device.

These heat losses may be calculated with sufficient accuracy in the following manner:

1. The heat loss through incombustibles of the corpse may be taken to be of the same order of magnitude as those of the coke (7% of the upper heating value of the corpse),[588] which gives us (Gusen Furnace; see Subchapter 10.3):

   normal: 292,200 kcal · 0.07 ≈ 20,450 kcal [154]
   average: 164,400 kcal · 0.07 ≈ 11,500 kcal
   lean: 71,200 kcal · 0.07 ≈ 5,000 kcal

2. H. Keller based his calculations on a value of the specific heat of 1 kcal kg^{-1} $°C^{-1}$, as applies to water (H. Keller 1929, p. 3), which appears to be too high, however (see H. Keller's own remark to that effect quoted on p. 111 and marked with "[sic]"). Assuming a specific heat of 0.8, we get for the various types of corpse's combustible dry matter (see Subsection 10.2.3.3):

   normal: $2 \cdot 21.0\ kg \cdot 0.8\ kcal\ kg^{-1}\ °C^{-1} \cdot (850°C - 20°C) \approx 27{,}900\ kcal$ [155]
   average: $2 \cdot 11.9\ kg \cdot 0.8\ kcal\ kg^{-1}\ °C^{-1} \cdot (850°C - 20°C) \approx 15{,}800\ kcal$
   lean: $2 \cdot 5.3\ kg \cdot 0.8\ kcal\ kg^{-1}\ °C^{-1} \cdot (850°C - 20°C) \approx 7{,}000\ kcal$

3. As the heating value of coke is not something obtained by precise calorimetric measurements, but the result of a theoretical calculation, the coke will absorb, up to the ignition temperature,[589] a certain amount of heat[590] which, in our case, is:

   normal: $2 \cdot 25.6\ kg \cdot 0.24\ kcal\ kg^{-1}\ °C^{-1} \cdot (700–20)°C \approx 8{,}400\ kcal$ [156]
   average: $2 \cdot 30.6\ kg \cdot 0.24\ kcal\ kg^{-1}\ °C^{-1} \cdot (700–20)°C \approx 10{,}000\ kcal$
   lean: $2 \cdot 35.5\ kg \cdot 0.24\ kcal\ kg^{-1}\ °C^{-1} \cdot (700–20)°C \approx 11{,}600\ kcal$

4. In the Gusen Furnace, as in those at Birkenau, the corpse was introduced by means of a metal stretcher as described in Chapter 7, which weighed about 50 kilograms. As the device went into the muffle for the equivalent of 75% of its mass and stayed there for several minutes, we may assume, taking into account the low thickness of the metal parts, that this portion heated up to about 300°C,[591] hence this heat loss, independent of the kind of corpse, is:

---

[588] "The experiments done by Debette show that the heat loss due to incomplete combustion is around 2% when the smoke is perfectly clear, but may reach 10% when the smoke is black and dense." Bordoni 1918, p.39.

[589] The ignition temperature of coal is around 700°C.

[590] "We must remember that on introduction the coal is cold and must be heated to ignition temperature by draining heat from the hearth; if all of the coal is added at once, the heat so drained may even perturb the combustion of the coal already burning." Cantagalli 1940, p. 111. As an internet search reveals, the heat capacity of coke varies with the type of coal, the degree of coking, and significantly with the temperature. The value used here (0.24 kcal kg^{-1} $°C^{-1}$) is an average. The Gusen coke consumption for normal and lean corpses was taken from Table 10 multiplied by a factor 1.1 resulting from the average coke consumption in the Gusen Furnaces (30.6 kg/corpse) being 10% higher than that calculated for the Auschwitz Furnaces (27.8 kg).

[591] Heat radiation to the underside of the stretcher, a surface area of some 0.5 m^2 resting on the grate bars of the muffle, was the equivalent of about 650 kcal/min or 1,300 kcal within 2 minutes, which would have resulted in heating the stretcher to about 300°C. For the heat capacity of iron see

$$2 \cdot 0.75 \cdot (50\ \text{kg}) \cdot 0.11\ \text{kcal kg}^{-1}\ ^\circ\text{C}^{-1} \cdot (300^\circ\text{C} - 20^\circ\text{C}) \approx 2{,}300\ \text{kcal} \quad [157]$$

Assuming a duration of an hour for the cremation, the total value of these heat losses is therefore roughly:

normal: 20,450 + 27,900 + 8,400 + 2,300 ≈ 59,000 kcal/hr [158]
average: 11,500 + 15,800 + 10,000 + 2,300 ≈ 39,600 kcal/hr
lean: 5,000 + 7,000 + 11,600 + 2,300 ≈ 25,900 kcal/hr

In percent of the unknown value x in the heat balance of the Gusen Furnace (Eqs. 142, 137, 146) this is:

normal: 59,000 ÷ 364,589 = 16.18% [159]
average: 39,600 ÷ 266,649 = 14.85%
lean: 25,900 ÷ 215,079 = 12.04%

As the above figures are approximations, we assume rounded figures when calculating the heat loss due to the combustion air:

normal: 364,600 – 59,000 = 305,600 kcal/hr [160]
average: 266,600 – 40,000 = 226,600 kcal/hr
lean: 215,100 – 26,000 = 189,100 kcal/hr

This amount of heat is needed to heat the following amount of air from 20°C to 750°C:

normal: 305,600 kcal ÷ 0.329 kcal°C^{-1}m^{-3} · 730°C = 1,272.4 Nm³ [161]
average: 226,600 kcal ÷ 0.329 kcal°C^{-1}m^{-3} · 730°C = 943.5 Nm³
lean: 189,100 kcal ÷ 0.329 kcal°C^{-1}m^{-3} · 730°C = 787.4 Nm³

In the Topf double-muffle furnace at Auschwitz the heat needed to raise this volume of air to 700°C amounts to:

normal: 1272.4 Nm³ · 0.328 kcal°C^{-1}Nm^{-3} · 680°C ≈ 283,800 kcal [162]
average: 943.5 Nm³ · 0.328 kcal°C^{-1}Nm^{-3} · 680°C ≈ 210,400 kcal
lean: 787.4 Nm³ · 0.328 kcal°C^{-1}Nm^{-3} · 680°C ≈ 175,600 kcal

Expressed in percent of the x values listed in Table 11:

normal: 283,800/327,800 ≈ 86.6% [163]
average: 210,400/247,630 ≈ 85.0%
lean: 175,600/206,100 ≈ 85.2%

We may therefore conclude that the total volume of combustion air for the Topf double-muffle furnace at Auschwitz was:

normal: 1272.4 Nm³ + 2 · 23.3 kg · 7.17 Nm³/kg · 1.5[592] = 1,774 Nm³ [164]
average: 943.5 Nm³ + 2 · 27.8 kg · 7.17 Nm³/kg · 1.5 = 1,541 Nm³
lean: 787.4 Nm³ + 2 · 32.3 kg · 7.17 Nm³/kg · 1.5 = 1,482 Nm³

The excess-air ratio was therefore:[593]

$$\frac{1{,}542\ \text{m}^3}{2[\text{corpses}] \cdot 87\ \text{m}^3/\text{corpse} + 2[\text{corpses}] \cdot 27.8\ \text{kg} \cdot 7.17\ \text{Nm}^3/\text{kg}} \approx 2.7 \quad [165]$$

The initial table must therefore be corrected as follows:

---

www.engineeringtoolbox.com/specific-heat-metals-d_152.html.

592 Excess-Air Coefficient, see p. 116.

593 For the theoretical combustion volume per average corpse of 87 m³ see p. 362.

Table 12: Corrected Total Combustion Air Need for Various Corpses

TYPE OF CORPSE	TOTAL AIR	THEORETICAL AIR VOLUME	EXCESS-AIR FACTOR
Normal	1,774 m³	644 m³	2.75
Average	1,541 m³	572 m³	2.69
Lean	1,482 m³	540 m³	2.74

10.6. Heat Balance of the Topf Triple-Muffle Furnace

The triple-muffle furnace consists of a furnace with two muffles to which a center muffle has been added. The two outer muffles operated as in a double-muffle furnace but discharged their off-gases into the center muffle. As the furnace operated with a rather high excess-air ratio, the off-gas contains a certain amount of oxygen which could be used for the combustion of the corpse in the center muffle, thus bringing about a certain saving in coke consumption. The following table gives the volume of air which passed on into the center muffle from the outer ones (available air):

Table 13: as Table 12, plus Available Uncombusted Air for Center Muffle

TYPE OF CORPSE	TOTAL AIR	THEORETICAL AIR VOLUME	EXCESS-AIR RATIO	AVAILABLE AIR
Normal	1,774 m³	644 m³	2.75	1,130 m³
Average	1,541 m³	572 m³	2.69	969 m³
Lean	1,482 m³	540 m³	2.74	942 m³

In the case of a normal corpse, for example, 1,130 Nm³ of uncombusted air entered the center muffle, whereas the combustion air of the corpse and the coke for each of the outer muffles amounted to only (1,774÷2 =) 887 Nm³ of air.

However, the amount of coke consumed by the two outer muffles could not be less than in the double-muffle furnace; rather, it had to be slightly more, as they had greater heat losses by radiation and conduction (see Eq. 127, p. 357, compared to Eq. 131, p. 360). For example, the cremation of a normal corpse in the outer muffles required this much coke:

$$23.3\ \text{kg} + \frac{45{,}100\ \text{kcal/hr} - 39{,}000\ \text{kcal/hr}}{2 \cdot 3{,}640\ \text{kcal/kg}} \approx 24.1\ \text{kg} \qquad [166]$$

Furthermore, in the center muffle, there are various other sources of air:

– Air entering the muffle during the introduction of the corpse.
– False air entering through the cracks around the doors and closures.
– Air coming from the blower (*Druckluftgebläse*) which could not be individually controlled and thus fed air simultaneously into all three muffles.

On the other hand, a possible overheating of the center muffle does not affect the overall heat balance in a significant manner, because, while the center muffle heats up essentially by radiation, the two outer muffles heat up mainly by conduction. Thus, even if the center muffle had been 200°C hotter than the outer muffles (1000°C instead of 800°C), the heat loss through conduction (V_l) would be minor:

$$V_l = \frac{\lambda \cdot F \cdot \Delta T}{d} \qquad [167]$$

With the heat conductivity of refractory brick $\lambda = 0.73$ (see Subsection 10.2.2.1), the internal contact surface $F = (2 \cdot 2\text{ m} \cdot 0.3\text{ m} =)$[594] 1.2 m², the thickness of that material $d = 0.25$ m, and the assumed temperature difference ΔT of 200°C, we obtain:

$$\frac{0.73\text{ kcal m}^{-1}\text{ °C}^{-1}\text{ hr}^{-1} \cdot 1.2\text{ m}^2 \cdot 200\text{°C}}{0.25\text{ m}} \approx 700\text{ kcal/hr}$$

to the outer muffles while, at the same time, leading to a drastic drop in furnace efficiency due to the high temperature of the exhaust gases[595] and a correspondingly drastic increase in coke consumption.

Other factors also have a negative effect on the heat balance:

– As will be explained in Subchapter 10.10., the dwell time of the off-gases in the muffle is insufficient for a complete combustion of the unburnt gases, which means that the gases generated by the gasification of the corpse either burn in the flue ducts or leave the chimney unburnt in the form of smoke.
– Furnace management was effected by means of a single flue-gas damper for all three muffles. The combustion of the corpses thus cannot be controlled individually for each muffle, and thus leads to an increase in the portion of unburnt gases.

From the above it can clearly be seen that the combustion air was not proportional to what was available in the double-muffle furnace. Hence one cannot calculate a heat balance along the same lines. However, knowing, as we do, that consumption of coke for three corpses could not have been less than what can be observed for the two outer muffles, we are able to calculate a minimum theoretical limit for the consumption.

We know that the triple-muffle furnace's heat loss by radiation and conduction was 61,220 kcal/hr, and that of the center muffle was 16,120 kcal/hr [Eqs. 129 & 130, p. 359]. Theoretically, the triple-muffle furnace behaved like a double-muffle furnace with the center muffle inserted, hence resulting in an additional heat loss of 16,120 kcal/hr. The triple-muffle furnace's theoretical minimum consumption of coke was therefore equal to that of the double-muffle furnace plus that of the center muffle. We therefore add to the double-muffle furnace's coke consumption that caused by the additional heat loss of the triple-muffle furnace due to its center muffle, and apply this to three instead of just two corpses:

Normal Corpse

$$\left(23.3 + \frac{16{,}120\text{ kcal/hr}}{2 \cdot 3{,}640\text{ kcal/kg}}\right) \cdot \tfrac{2}{3} \approx 17\text{ kg per corpse.} \qquad [168]$$

[594] 2 muffle walls, 2 m long, 0.3 m high from the muffle grate to the beginning of the vaulted muffle ceiling.

[595] For a smoke temperature of 900°C, the efficiency would be around 45%.

Average Corpse

$$\left(27.8 + \frac{16{,}120 \text{ kcal/hr}}{2 \cdot 3{,}640 \text{ kcal/kg}}\right) \cdot \tfrac{2}{3} \approx 20 \text{ kg per corpse.} \quad [169]$$

Lean Corpse

$$\left(32.3 + \frac{16{,}120 \text{ kcal/hr}}{2 \cdot 3{,}640 \text{ kcal/kg}}\right) \cdot \tfrac{2}{3} \approx 23 \text{ kg per corpse.} \quad [170]$$

The amount of coke for lean corpses corresponds well to the maximum hourly coke throughput rate of the two gasifiers, split up for the three muffles:

$$\frac{2 \cdot 35 \text{ kg/hr}}{3 \text{ lean corpses}} = 23.3 \text{ kg per hour and corpse} \quad [171]$$

As previously explained, the above calculation of the coke consumption is the theoretical *minimum*. In practice, if the hourly coke consumption was 70 kg, and if the cremation lasted one hour on average, 23.3 kg of coke was also the real consumption for the cremation of a normal corpse. In this case the excess heat (since by hypothesis the furnace was in thermal equilibrium and did not absorb additional heat) was lost in the fireplace and through the chimney.

In practice only the cremation of a normal corpse lasted one hour, though. We know from experience that the cremation of lean corpses lasted longer, as much as 1.5 hours or more. As a result, the *actual* coke consumption during the cremation of lean corpses was closer to (1.5 hr · 23.3 kg ≈) 35 kg or even higher in the triple-muffle furnaces.

We clearly have reached here the limits of our extrapolations, but we may assume that additional heat losses due to excess air in the center muffle are minor compared to the contribution of the two lateral muffles.

Hence, for simplicity's sake I abstain from listing any concrete contribution to the excess air by the center muffle in the following table, and indicate only that it would be greater than zero. We thus obtain for the triple-muffle furnace the following *minimum* excess-air ratios:

Table 14: Combustion-Air Availability in Auschwitz Triple-Muffle Furnace

TYPE OF CORPSE	AIR OUTSIDE MUFFLE	THEORETICAL AIR	CENTER MUFFLE AIR	EXCESS-AIR RATIO
Normal	1,774 m³	810 m³	> 0 m³	> 2.19
Average	1,541 m³	671 m³	> 0 m³	> 2.30
Lean	1,482 m³	588 m³	> 0 m³	> 2.52

In the letter Kurt Prüfer wrote on 15 November 1942 to the owners of the Topf Firm, Ludwig and Ernst-Wolfgang Topf, he stated that the triple-muffle furnaces designed by him, which had been set up in the Buchenwald Crematorium, had shown a performance one third higher than what he had expected.[596] The cause of this decrease in coke consumption can only be what we have set out

[596] APMO, BW 30/46, p. 18.

above. As Prüfer had based himself on a grate-throughput rate of 70 kg of coke per hour for the two gasifiers under natural draft, a reduction of one third corresponds to 46.67 kg of coke per hour, or 15.5 kg of coke for each muffle. In view of the fact that a cremation lasted one hour as well, this consumption also refers to one cremation in one muffle and is thus close to what we have calculated for a normal corpse.

10.7. Heat Balance of the Topf 8-Muffle Furnace

The 8-muffle furnace consisted of four pairs of independent muffles, but the two muffles of each pair were connected. Because in this case, too, the combustion products of the first muffle passed on through the second, what I said earlier for the triple-muffle furnace applies here as well: the off-gas from the first muffle contained an amount of oxygen theoretically high enough for the combustion of the corpse in the second muffle, as shown in the table below:

Table 15: Combustion-Air Data for Auschwitz 8-Muffle Furnace

TYPE OF CORPSE	TOTAL AIR*	THEORETICAL AIR*	AVAILABLE AIR
normal	887 m³	– 322 m³ =	565 m³
average	771 m³	– 286 m³ =	485 m³
lean	741 m³	– 270 m³ =	471 m³

* Half of values of Table 12, p. 372

In this case as well, a possible overheating of the second muffle could not affect, in a relevant manner, the overall heat balance, because the coke consumption could not be less than for the first muffle. We will therefore assume also for this furnace a *minimum theoretical consumption* corresponding to half of that for the double-muffle furnace:

– Normal corpse: 23.5/2 = 11.75 kg, rounded to 12 kg
– Average corpse: 28.0/2 = 14.00 kg
– Lean corpse: 32.5/2 = 16.25 kg, rounded to 16 kg

Table 16: General summary of the coke consumption

TYPE OF CORPSE	DOUBLE-MUFFLE	TRIPLE-MUFFLE	8-MUFFLE
normal	23.3 kg	≥17 kg	≥12 kg
average	27.8 kg	≥20 kg	≥14 kg
lean	32.3 kg	≥23 kg	≥16 kg

10.8. Observations on the Coke Consumption of the Triple- and 8-Muffle Furnaces

The *Aktenvermerk* (file memo) of 17 March 1943, written by the civilian employee Jährling and established "according to data supplied by Topf & Söhne"[597] contains an estimate of the coke consumption of the four Birkenau Crematoria. This document requires some explanations.

[597] APMO, BW 30/7/34, p. 54. Cf. Document 264.

The heading "*10 Feuerungen = 350 kg/stdl.*" (10 hearths = 350 kg/hr) means that the five triple-muffle furnaces located in each of the Crematoria II and III had a total of 10 gasifier hearths, two per furnace, each with a grate throughput rate of 35 kg/hr of coke, just as the 8-muffle furnaces of Crematoria IV and V had four hearths each, each one with a throughput of 35 kg of coke per hour.

The reduction of coke consumption by 1/3 "*bei Dauerbetrieb*" (in continuous operation) is based on the fact that, in this case, consumption was considerably lower than what was needed in discontinuous use.

The letter by Topf giving the data mentioned by Jährling has not been found, but it is improbable that it contained a calculation similar to the one presented by the Central Construction Office employee. The computation, although basically correct, is, in fact, somewhat misleading, as it refers to the grate throughput rather than to the number of corpses cremated, which would have been more-pertinent and more-useful in practice, as was the case in the chart giving coke consumptions as a function of the number of cremations in civilian crematoria which was presented in Unit I (cf. Document 90).

In line with such a chart, applicable only to *a few* civilian furnaces, Topf would surely have referred to a reduction of coke consumption with an increasing number of corpses cremated and an increasing frequency of cremations, as was shown in actual operation for the Gusen Furnace.

Between 26 September and 15 October 1941, over a total span of 20 days, 193 corpses were cremated in the Gusen Furnace on ten days of operation. On average, cremations took place every other day, with 19 corpses cremated during each cycle and a consumption of 47.5 kg of coke per corpse.

Between 26 and 30 October, over a span of five days, 129 corpses were cremated in the Gusen Furnace. Cremations took place each day, with 26 corpses being cremated daily on average, leading to a coke consumption of 37.2 kg per corpse.

Between 31 October and 12 November, a span of 13 days, 677 corpses were cremated in the Gusen Furnace. Cremations took place each day, for an average number of 52 corpses cremated daily and a consumption of 30.6 kg of coke per corpse.

Thus, moving from a discontinuous operation (cremations every other day) and relatively few cremations (19 per day)[598] to a continuous operation (daily cremations) with many cremations (52 per day), specific coke consumption dropped from 47.5 to 30.6 kg, *i.e.* to [(30.6÷47.5) · 100 =] 64.42%, for a saving in coke of a little more than one third.[599] In practice, if the cremation of 20 corpses required (20 · 47.5 =) 950 kg of coke in the first case, only (950 · 0.6442 =) 612 kg – or (30.6 · 20 =) 612 kg – were needed in the third case. The difference of 950 – 612 = 338 kg was consumed in heating up the furnace after it had cooled for more than 24 hours.

---

[598] The reader should remember that the furnace had two muffles and 19 cremations per day, thus corresponded to about 10 loadings per muffle.

[599] For an intermediate case of daily, but not-very-numerous cremations, coke saving would have been about 1/6.

In the same way, in the file memo of 17 March 1943, the reduction in coke consumption of one third in 12 hours of operation – from 4,200 to 2,800 kg – can only mean that the difference of 1,400 kg was used for heating the five furnaces,[600] and the remainder of 2,800 kg concerned the cremations themselves. This does not mean, however, that the normal grate-throughput rate would drop by one third in continuous operation.

We must remember that the gasifiers could not be controlled like a gas burner, which can easily be turned on and off in line with the cremation demand at hand. The coke on the grates burned continuously for the whole duration of the cremations. This can be seen very clearly in Document 47, in which the line "D" shows the hearth draft, curve "C" the chimney draft and the figures for "G" indicate the degree and duration of the opening of the combustion-air inlets of the gasifier.

After the preheating phase, when the furnace had reached its operating temperature, the curve of the hearth draft, logically, follows the curve of the chimney draft; the one maintaining itself, with minor fluctuations, around 10 mm of water column, the other, in a similar manner, around 5 mm. In line with the brief periods during which the gasifier door was open, the chimney draft then touched a level of 15 mm; that of the hearth, 10 mm of water column. In the long intervals in between, when this door stayed shut, the chimney normally had a draft of 10 and the hearth of 5 mm water column. This demonstrates that the normal combustion rate of the hearth was about 33.3 kg of coke[601] per hour all through the cremation, without major differences between preheating and cremating periods.

As I explained in Subchapter 8.3, the normal grate-throughput rate of 120 kg h^{-1} m^{-2} could be increased by increasing the draft by means of a draft enhancer, but it could not be reduced to any significant degree. It follows that, although the triple-muffle and the 8-muffle furnaces theoretically had an average coke requirement of [(17+20+23)÷3 =] 20 and [(12+14+16)÷3 =] 14 kg of coke per hour respectively, actual consumption in continuous operation was as follows:

Table 17: Actual Coke Consumption of Triple- and 8-Muffle Furnaces

	GRATE-THROUGHPUT RATE OF HEARTHS	COKE PER HOUR, MUFFLE & CORPSE
Triple-muffle furnace	70 kg/hr	23.3 kg
8-muffle furnace	140 kg/hr	17.5 kg

If, for greater coke economy, one had wanted to slow down the combustion on the hearths, it would have been necessary to reduce the chimney draft, but that would have affected the cremation as well and lengthened it, which would, in turn, have led to an increase in the consumption of coke per cremation in proportion to the increasing duration of the cremation.

[600] By this, we mean preheating all of the furnace brickwork to a steady state.

[601] This is obtained by dividing the coke consumption (457 kg) by the total operating time of the furnace (13 hours and 42 minutes).

10.9. A Comparison with the Kori Furnace at the Westerbork Camp and the Kori Slaughterhouse Furnaces

Thanks to its design, the Kori Furnace at the Westerbork Camp showed a better performance than the Topf Furnaces. As there were many corpses of children among the corpses cremated, it is not possible to deduce with certainty the amount of coke needed for an average adult corpse. If we base ourselves on the cremations listed in Subchapter 8.4. for which the coke consumption is documented, we find a total weight of 3,170 kg of coke for 163 cremated corpses, 43 of them children who together could be considered the equivalent in weight of six adult corpses. This yields an average coke consumption of about (3,170 ÷ (163–43+6) =) 25.2 kg per adult-corpse equivalent.

The minimum consumption is shown for 7 June 1943, 150 kg of coke for 13 corpses, among them two babies of 2 and 10 months, respectively. Such a low value can only be explained by assuming the use of a light-weight coffin of raw boards, such as the one shown in Photo 362.

This does not affect the heat balance of the Topf Furnaces, however, as the latter is based on the effective consumptions of the Topf Furnace at Gusen.

On the other hand, the data from the Kori Furnaces for slaughterhouses agree rather well with the data from the Topf Furnace at the Gusen Camp and with those for the double-muffle furnace at Auschwitz, not only as far as consumption is concerned, but also with respect to duration of the cremations, as we can gather from the table below in which the results for different models of Kori Furnaces refer to an equivalent corpse of about 70 kilograms (see Section 9.2.1.):

Table 18: Kori slaughterhouse-furnace performance data for an average 70 kg corpse

FURNACE TYPE	COAL CONSUMPTION	DURATION OF CREMATION
1a	≈ 23.0 kg	≈ 63 min
1b	≈ 22.7 kg	≈ 62 min
2a	≈ 21.7 kg	≈ 60 min
2b	≈ 20.6 kg	≈ 58 min
3a	≈ 20.3 kg	≈ 57 min
3b	≈ 19.2 kg	≈ 54 min
4a	≈ 19.6 kg	≈ 52 min
4b	≈ 18.8 kg	≈ 50 min

The consumption figures refer to fueling with hard coal, which has a higher heating value than coke (7,500 kcal/kg on average). For coke, they would have to be increased by 3 to 3.7 kg in each case. Thus, the equivalent consumption of coke would become about 26.7 kg for a Type 1a Furnace, or 21.8 kg for a Type 4b Furnace.

10.10.Some Thermal Aspects of the Triple-Muffle Furnace

In Chapter 2, the fact was mentioned that the first electrically fired Topf Furnace set up in the Erfurt crematorium immediately presented a problem in that smoke formed during the cremations. An investigation of this phenomenon resulted in the following assessment (Weiss 1934, pp. 454f.):

> *"The smoke was not due to the fact that the carbon particles could not burn completely because of a lack of oxygen. The muffle had been designed to the lowest possible dimensions for avoiding waste of heat during preheating, and the carbon particles therefore had to burn in the flue ducts. On account of the very-strong enhanced draft of 12-24 mm of water column, the flue-gas velocity was high, and the dwell time of the particles in the flue ducts was thus too short. This residence time was insufficient to allow the particles to burn out completely; instead, immediately on entering the flue ducts they cooled down far enough to stop burning. This strong cooling of the fumes was aggravated by other factors. First of all, because of the high velocity in the narrow tubes of the preheater, the combustion air was insufficiently preheated, which meant that, from the very beginning, high flame temperatures could not be maintained at such a high excess air ratio.*
>
> *Secondly, because of the strong draft, the furnace drew in large amounts of false air through the cracks around the closures and on account of other defects of caulking which caused further cooling of the fumes. Thirdly, during the decomposition of the corpse, large amounts of water vapor were generated, which absorbed from the fumes the heat necessary for vaporization and cooled them still more. Thus, the oil vapors generated at the same time could no longer burn. Measurement of the discharge-gas temperatures proved conclusively that the flames, at best, were extinguished even before entering the flue duct."*

This phenomenon had already been observed by the engineer H. Keller who had noted, in connection with the Ruppmann Gasifier at the Biel Crematorium (H. Keller 1928, pp. 27f.):

> *"When combustible gases are generated by these processes, such as light or heavy hydrocarbons as they are called in the language of chemical engineering, they are immediately sucked up by the chimney and, for the most part, can no longer burn in the cremation chamber or the post-combustion chamber, but instead move on into the recuperator. If this part is hot enough,* [the hydrocarbons] *will ignite, and combustion will take place there.*
>
> *The lighter hydrocarbons will certainly finish their combustion in the post-combustion chamber, but for the heavier ones, present in larger quantities, at times even the recuperator is insufficient, and they will exit the chimney into the atmosphere in the form of smoke."*

To make matters clearer, we have to take a closer look at the thermal phenomena encountered here.

The intensity in space of a combustion, expressed as kcal per m^3 and h, is essentially a function of the amount of fuel burnt per hour, and the maximum intensity is controlled by the rate of combustion, which can be defined as the volumetric velocity of the spread of the flame per unit area; therefore, the combustion time must always be equal to or less than the residence time of the fuel in

the cremation chamber. If this condition is not fulfilled, the flame will extend beyond the cremation chamber, provided, of course, that conditions for combustion can be found there (Salvi, p. 217).

Thus, if the flow rate of a combustible-gas mixture in a combustion chamber is higher than its rate of combustion, the mixture will not completely burn in the cremation chamber but will continue to burn downstream of it if conditions there are favorable, or it will leave the installation unburnt if conditions are unfavorable.

In order to prevent any such emission into the atmosphere, modern cremation equipment has a post-combustion chamber for any such fumes.[602]

As an example, we may look at incinerators for urban waste. The operating temperature for such furnaces must be between 900 and 1000°C, with an optimum value around 950°C. The slag and the ash have softening points between 1050 and 1150°C;[603] if such a temperature is reached and maintained for a sufficiently long time, deposits and incrustations will form on the grates, on the walls of the incineration chamber and along the flue ducts, affecting the geometry of the installation and lowering its combustion performance.

The combustion products must remain in the post-combustion chamber for at least two seconds; the latter must be equipped with an auxiliary combustion device with automatic control in order to ensure that a minimum temperature of 950°C is maintained (Colombo, p. E740f.).

During the decomposition of a corpse in a cremation chamber, combustible gases such as carbon monoxide or light and heavy hydrocarbons will form, in addition to volatile carbon particles. The maximum ignition rate of most hydrocarbons in air under atmospheric conditions varies between 25 and 100 cm/sec, or, volumetrically, between 0.25 and 1 m³/sec (*Enciclopedia della Scienza*… 1963, vol. III. pp. 365f.). In normal practice, however, higher values will be used. This is true not only for incinerators, but also for crematoria. For the most-recent electrically heated cremation furnaces built by the Brown Boveri AG Co., a dwell time of 1.3 to 2.3 seconds in the post-combustion channels is maintained, with preheating to 800°C (see Unit I, Chapter 11). For the Therm-Tec Models SQC 300 and 400 Furnaces (Sherwood, Oregon, USA), this dwell time is 1.5 seconds (see Document 109a).[604]

Hence, for the necessary minimum dwell time of the gases generated during the decomposition of a body, we may assume 1.3 seconds.

The experiments carried out by the engineer H. Keller on the electrically heated furnace at Biel are an excellent example to illustrate this problem of heat engineering. During the cremation of a corpse weighing 110 kg on 26 September 1940, a maximum generation rate of 3,570 m³ of exhaust gas per hour at an

---

[602] Even the refuse-incineration furnace installed at the cemetery of Frankfurt/Main in Germany at the end of the 1930s had a post-combustion chamber for the fumes, located above the combustion chamber. Heinemann 1940, pp. 189f.

[603] Since ash is an amorphous mixture of various compounds, it does not have a sharply defined melting point, but softening occurs continuously over a wide temperature range.

[604] https://web.archive.org/web/20190218153821/http://thermtec.com/sites/default/files/pdf-library/SQC-400%20SPECS.pdf; …/SQC-300 SPECS_0.pdf

exhaust temperature of 380°C was observed 50 minutes after introduction of the corpse into the furnace (cf. Document 54). This rate corresponds to:

$$3{,}570\ \text{m}^3/\text{hr} \cdot \frac{273°\text{C}}{380°\text{C} + 273°\text{C}} = 1{,}492\ \text{Nm}^3/\text{hr} \qquad [172]$$

At 800°C inside the muffle, this corresponds to a volumetric rate in the muffle of:

$$1{,}492\ \text{Nm}^3/\text{hr} \cdot \frac{800°\text{C} + 273°\text{C}}{273°\text{C}} = 5{,}864\ \text{m}^3/\text{hr} \qquad [173]$$

or

$$\frac{5{,}864\ \text{m}^3/\text{hr}}{3{,}600\ \text{sec/hr}} = 1.63\ \text{m}^3/\text{sec.} \qquad [174]$$

The cremation chamber of the furnace in question, including the space below the grate, had a volume of some 2.5 m³, hence the average residence time of the fumes in the cremation chamber was 2.5÷1.63 = 1.53 seconds.

If we apply the same reasoning to the Topf double-muffle furnace, we obtain, for one muffle with one normal corpse and a cremation time of 60 minutes (see Table 12, p. 372), 1,774 Nm³ ÷ 2 = 887 Nm³ of dry fumes, which at 800°C becomes:

$$887\ \text{Nm}^3/\text{hr} \cdot \frac{800°\text{C} + 273°\text{C}}{273°\text{C}} = 3{,}486\ \text{m}^3/\text{hr} \qquad [175]$$

or on average:

$$\frac{3{,}486\ \text{m}^3/\text{hr}}{3{,}600\ \text{sec/hr}} = 0.97\ \text{m}^3/\text{sec.} \qquad [176]$$

This yields an average dwell time of:

$$\frac{1.4\ \text{m}^3}{0.97\ \text{m}^3/\text{sec}} = 1.44\ \text{seconds} \qquad [177]$$

This is the average time for the passage of the combustible gases through the cremation chamber.[605] This issue points out a serious flaw in the design of the Topf triple-muffle furnace.

We have seen in the preceding section that Engineer Prüfer, when designing the triple-muffle furnace, did not realize initially the advantage in heat consumption brought about by the passage of the fumes from the two outer muffles into the center one; but the fact that he gave to this muffle exactly the same dimensions as he had used for the outer muffles shows, moreover, that he had also not noticed a serious drawback of his design, directly related to the advantage it had: The gas volume which passed through the center muffle was more than twice that going through one muffle of the double-muffle furnace. As we have seen, the dwell time for such a muffle already touched the minimum of the combustion time of these gases; therefore, if one wanted to maintain in the cen-

[605] The varying intensity of smoke generation during a cremation could be compensated by a possible staggering of cremations.

ter muffle a dwell time equal to that applying to the double-muffle furnace, it would have been necessary to at least double the volume of the center muffle, in a similar fashion as, during the design of the smoke ducts of Crematoria II/III, it was provided that the cross-section of the smoke ducts was increased from 60 cm × 70 cm to 80 cm × 120 cm when two individual furnace flues merged into one chimney duct, as mentioned before, precisely because the exhaust gases from two furnace flues merged in each duct.

Prüfer, however, had not recognized this bottleneck. If he had wanted to obtain a complete combustion of all the gases in the center muffle of the designed size, he would have had to reduce the combustion rate of the corpse in that muffle by half. Taking the calculated *minimum* total gases flowing through the center muffle during the cremation of a lean and a normal corpses (see Table 14, p. 374), these 1,482 m³ and 1,774 m³ Nm³/hr speeds of dry fumes, respectively, became at 800°C:

$$\text{Normal: } 1{,}744\ \text{Nm}^3/\text{hr} \cdot \frac{800°\text{C} + 273°\text{C}}{273°\text{C}} = 6{,}855\ \text{m}^3/\text{hr} \qquad [178]$$

$$\text{Lean: } 1{,}482\ \text{Nm}^3/\text{hr} \cdot \frac{800°\text{C} + 273°\text{C}}{273°\text{C}} = 5{,}825\ \text{m}^3/\text{hr}$$

This is equivalent to:

$$\text{Normal: } \frac{6{,}855\ \text{m}^3/\text{hr}}{3{,}600\ \text{sec/hr}} = 1.90\ \text{m}^3/\text{sec} \qquad [179]$$

$$\text{Lean: } \frac{5{,}825\ \text{m}^3/\text{hr}}{3{,}600\ \text{sec/hr}} = 1.62\ \text{m}^3/\text{sec}$$

This led to an average residence time in the center muffle of:

$$\text{Normal: } \frac{1.5\ \text{m}^3}{1.9\ \text{m}^3/\text{sec}} = 0.79\ \text{sec} \qquad [180]$$

$$\text{Lean: } \frac{1.5\ \text{m}^3}{1.62\ \text{m}^3/\text{sec}} = 0.93\ \text{sec}$$

This means that the heavier hydrocarbons which formed during the decomposition of the corpse located in the center muffle did not have enough time to burn out completely and left the muffle unburnt. If the temperature in the flue duct was lower than the ignition temperature of these gases, smoke would have been generated. But if the temperature was high enough, the off-gas could burn out in the duct, potentially damaging it, as in fact happened at the end of March 1943.

10.11.On Claims of Flaming Chimneys

The question of flaming chimneys, which some witnesses claim to have observed, is directly linked to the matters dealt with in the preceding subchapter: could the combustion of unburnt gases have moved through the flue ducts to the atmosphere and thus given rise to the appearance of flaming chimneys? Let us first look at this question in connection with Crematoria II and III.

A calculation based on the actual conditions in these crematoria shows that the phenomenon could not occur, even under the most favorable conditions, *i.e.* in the case of three normal corpses in the pair of furnaces having the shortest flue duct, without taking the volume of the cremation chamber into account. The third and fourth furnaces of these crematoria had flue ducts of a cross-sectional area of 0.42 m² (0.6 m × 0.7 m) and respective lengths of some 6.5 and 10.5 m. Both opened into the duct of the central forced-draft device, which had a length of 2 m and a cross-section of 0.8 m × 1.2 m, which itself opened into the central duct of the chimney. The latter was 15.46 m high and had a cross section of 0.8 m × 1.2 meters.

Hence, the average section of the shortest duct was:

$$\frac{6.5\ \text{m} \cdot 0.42\ \text{m}^2 + \frac{17.5\ \text{m} \cdot 0.96\ \text{m}^2}{2}}{24\ \text{m}} = 0.46\ \text{m}^2. \qquad [181]$$

In this calculation, we have divided by two the cross-sectional area of the duct common to the forced-draft device and the chimney duct, because the gas volume doubled on account of the gas coming from the fourth furnace; we have also given the chimney an approximate height of 15.5 meters, so that the overall length of the flue duct plus the chimney duct is 24 meters.

Three normal corpses and the necessary amount of coke will generate 1,774 Nm³ of dry fumes and 230.5 Nm³ of water vapor,[606] for a total of almost 2,005 Nm³ of moist gas, which, at 700°C, had a volume of about:

$$2{,}005\ \text{Nm}^3 \cdot \frac{700°\text{C} + 273°\text{C}}{273°\text{C}} = 7{,}146\ \text{m}^3. \qquad [182]$$

If that gas is discharged over a time span of one hour, the average gas velocity thus becomes:

$$\frac{7{,}146\ \text{m}^3/\text{hr}}{0.46\ \text{m}^2 \cdot 3{,}600\ \text{sec/hr}} \approx 4.3\ \text{m/sec}. \qquad [183]$$

Hence the dwell time of the gas within the discharge ducts is:

$$\frac{24\ \text{m}}{4.3\ \text{m/sec}} = 5.5\ \text{sec}. \qquad [184]$$

This time is more than sufficient for the combustion of any unburnt gases, all-the-more-so as we have not even included the volume of the three cremation chambers themselves.

In order to verify experimentally the validity of this calculation, I have carried out a number of experiments involving the incineration of animal fats in a field furnace which gave rise to the phenomenon of a flaming chimney. The field furnace had two grates, the lower one for wood (the hearth), and the upper one for the fat. Photo 368 shows the result of an experiment carried out on 21 October 1994.

---

[606] See list on page **Error! Bookmark not defined.**: 3 corpses · (20.23 Nm³ + 56.60 Nm³) = 230.5 Nm³.. For a simplification of the calculations, we assume the dry fumes to be the equivalent of the combustion air.

On the upper grate of the field furnace, the author placed an aluminum tray (33 cm × 25 cm × 5 cm) containing 400 grams of lard (pork fat). Then he lit the wood piled up on the lower grate, partly blocking the opening of the combustion chamber with a block of tuff.

After melting, the lard started to boil, and the vapors caught fire immediately. The flames were visible a few centimeters above the surface of the boiling fat, with the latter remaining clearly visible. In the most-intense phase of combustion, the flames shot out of the chimney to a height of one and a half meters above its mouth and more than two meters above the tray with the boiling fat. Combustion took about five minutes.

The explanation of the phenomenon is as follows: the volumetric velocity of the gases which developed from the decomposition of the fat was higher than their combustion velocity, *i.e.* their residence time in the combustion chamber was lower than the time needed for their complete combustion, which then took place outside the combustion chamber and even above the chimney.

In order to verify this explanation, the author then carried out two more combustion experiment with animal fat:

1. Combustion Chamber with a Short Chimney (10 January 1995)

The experiment was carried out in a field furnace of tuff blocks with two grates, the lower one for wood as fuel, the upper one for the fat. The combustion chamber measured about 0.05 m³, and possessed a chimney 0.54 m high with a cross-sectional area of 0.27 m × 0.27 m, set at a level of 10 cm above the upper grate. The author placed an aluminum tray (17 cm × 22 cm) containing 200 grams of lard on this grate. He then loaded the lower grate with wood and lit it. After a few minutes, the boiling fat caught fire, and tall flames shot out of the chimney up to a level of 70 cm above its mouth (Photo 369). Combustion of the fat took three minutes, and was most-intense for about two minutes and 45 seconds.

2. Combustion Chamber with a Long Chimney (10 January 1995)

The author then removed one layer of tuff blocks from the chimney and placed there an ordinary stove pipe of a length of 2.10 m and a cross-section of 40 cm × 20 cm, thus obtaining a total volume of some 0.2 m³ for the combustion chamber. He then placed on the upper grate an aluminum tray identical to the one used in the preceding experiment, but containing 300 grams of lard. He then loaded the hearth grate with wood and lit it, whereupon the fat again caught fire rapidly, but this time without any flames or isolated flame jets above the chimney (Photo 370). Combustion of the fat took three minutes and 45 seconds, including three minutes and 30 seconds of intense combustion.

3. Conclusions

The two experiments were carried out under similar conditions, except, of course, for the presence of the stovepipe in the second case. In spite of the fact that in the latter experiment more fat was used, no flames appeared above the

chimney, because the gases which developed during the decomposition of the fat had at their disposal a combustion chamber four times as large and were thus able to burn out completely within the chimney.

As we are dealing here with physico-chemical phenomena, the results are applicable *mutatis mutandis* to the Birkenau Crematoria.

4. Crematoria II and III

Volume of shortest flue duct (including chimney duct):

$$0.46\ m^2 \cdot 24\ m = 11.04\ m^3 \approx 11\ m^3 \quad [185]$$

Combustion chamber:

$$1.5\ m^3 \cdot 3 = 4.5\ m^3 \quad [186]$$

Total volume:

$$(11\ m^3 + 4.5\ m^3) = 15.5\ m^3 \quad [187]$$

a) For the First Experiment:

During the first experiment we had 0.2 kg of fat in a total combustion volume of 0.05 m³ burning within three minutes, which amounts to 4 kg of fat burning within an hour in this volume, and to 80 kg of fat per hour and m³.

Hence, the appearance of flames out of the chimneys of Crematoria II & III would have required at least the combustion in the triple-muffle furnace closest to the chimney of

$$80\ kg/hr/m^3 \cdot 15.5\ m^3 = \text{some } 1{,}240\ kg \text{ of fat per hour} \quad [188]$$

b) For the Second Experiment:

During the second experiment we had 0.3 kg of fat in a total combustion volume of 0.2 m³ burning within four minutes, which amounts to 4.5 kg of fat burning within an hour in this volume, and to 22.5 kg of fat per hour and m³.

In this case, no appearance of any flames out of the chimneys of Crematoria II & III would have occurred in case of the combustion in the triple-muffle furnace closest to the chimney of

$$22.5\ kg/hr/m^3 \cdot 15.5 \approx 350\ kg \text{ of fat per hour.} \quad [189]$$

Hence, when burning some 350 kg of fat per hour in the three muffles of the furnace mentioned, no flames would have formed above the chimney.

We are speaking here of *pure fat*, which means that from the cremation of three corpses in one hour in the three muffles of the furnace mentioned, it would not have been possible to cause the appearance of flames above the chimney. Actually, the fat content of a body of 70 kg is about 25 kg, and 350 kg would thus have corresponded to the fat content of 42 corpses, or 14 per muffle and hour.

We are not taking into account here the protein content of the corpses, because proteins have a considerably lower combustion rate than fats.

5. Crematoria IV and V

Crematoria IV and V had two chimneys each. Each chimney was linked to a group of four muffles. The total volume available to the combustion gases (combustion chamber, flue duct, chimney duct) was about 18 m³. In line with the preceding calculation, we would have:

a) For the First Experiment:

80 kg of fat per 1 m³ of the combustion chamber in one hour means for Crematoria IV & V:

$$80 \text{ kg/hr/m}^3 \cdot 18 \text{ m}^3 = 1{,}440 \text{ kg of fat per hour for four muffles} \quad [190]$$

Appearance of flames would have been possible, if some 1,440 kg of fat or more had been burned in one hour.

b) For the Second Experiment:

22.5 kg of fat per 1 m³ of the combustion chamber in one hour means for Crematoria IV & V:

$$22.5 \text{ kg/hr/m}^3 \cdot 18 = 405 \text{ kg of fat per hour for four muffles} \quad [191]$$

Flames would therefore not even have appeared above the chimney if over 100 kg of pure fat had been burned in *each* of the four muffles in one hour, corresponding to the fat content of 12 corpses per muffle and hour.

6. Final Remarks

The above calculations are based on a time of one hour, but it is obvious that the combustion of *all* of the fat contained in the corpses would have taken much less time than one hour. We must however take into account that the combustion of the corpse fat did not take place continuously, unlike the combustion in the above experiments; outer and inner fat would liquefy, gasify and burn in line with the processes of vaporization and combustion, therefore the combustion of *all* of the fat contained in a corpse required less than 1 hour, but at least 30 minutes.

This does not affect the results, however, as for Crematoria II and III the upper limit for visible flames above the chimney would still be 175 kg of fat in 30 minutes, as opposed to 25 kg actually burned; for Crematoria IV and V, the figures would be 202.5 kg of fat in 30 minutes against some 34 kg actually available.

What we have tried to show here does not mean that flames visible above the chimneys were altogether impossible, but that this was impossible in *direct* relation to a cremation, *i.e.* as a function of corpses being cremated. It was, on the other hand, possible in an *indirect* relation with the cremation, namely in connection with the coke on the furnace grates.

It is known that the incomplete combustion of carbonaceous fuel will generate carbon particles which will adhere to the walls of the chimney ducts in the form of soot. Under favorable conditions (a sufficiently thick layer of soot and a

temperature high enough), the soot will ignite and lead to the phenomenon of a flaming chimney.

Before World War Two, when domestic heating was done almost exclusively with wood and coal, this phenomenon was so widespread that on occasion it was caused intentionally to be studied from a scientific point of view. Experiments of this kind were, for example, carried out in a chimney duct of a nearly abandoned four-story building in Berlin in early 1933 (Kristen 1933, pp. 83-85). The temperature chart for this experiment (Document 265) shows that 95 minutes after the ignition of the soot on the ground floor, at a level of 1 m above the chimney base, the temperature in the chimney duct reached 1060°C.

This is not really surprising, because soot is essentially carbon, which has an ignition temperature of 700°C.

Obviously, the phenomenon would not be continuous, but occur only on occasion when, after a certain time, the soot layer had once again become thick enough.

11. The Cremation Furnaces Built by Other German Companies: Kori, Ignis-Hüttenbau and Didier

11.1. Historical Remarks Concerning the H. Kori Co. of Berlin

Topf's most active competitor in the field of cremation furnaces for the German concentration camps was the Hans Kori Co. located in Berlin. The historical review of Kori's cremation furnaces presented below, besides being of a certain value as far as the history of this technology is concerned, is also a useful means for assessing the technical status of the Topf furnaces.

Founded in 1887, the Kori Co. specialized in the design and construction of furnaces for the disposal of animal residue (*Tierleichen-Verbrennungsöfen*). The first such device was built in 1892 at the Nuremberg municipal slaughterhouse. By 1901, the company had become so well-known that Dr. Weyl from the medical association of the Prussian province of Brandenburg turned to Kori for solving the sanitary problems which had arisen in connection with a typhus outbreak in that province (cf. p. 148). In 1905, Kori could already boast of having built 55 furnaces for the disposal of animal carcasses, a figure which would rise to 160 over the nine years to come (Kori 1924, p. 115).

I have described the main models of this type of equipment manufactured by Kori at that time in Chapter 10 of Unit I (cf. Documents 98-100). Later on, the firm branched out into the field of incineration plants for all types of refuse. In 1927, Kori sold some 3,500 such units (Documents 266-268).

Although Hans Kori had made an important contribution to the cremation of human corpses in Germany when he managed to get the Prussian Ministry of the Interior to change the law on cremations of 14 September 1911 by the Decree of 24 October 1924 (cf. pp. 63f.), his own company went into the market segment of cremation furnaces rather late, at a time when the German market

was solidly dominated by four companies: Richard Schneider/Didier of Stettin, Gebrüder Beck of Offenbach, J.A. Topf & Söhne of Erfurt, and the Wilhelm Ruppmann Company of Stuttgart. While the first two were in clear decline, Topf experienced a steep rise in sales.

Kori managed to break into the market, albeit with some difficulty, and installed five furnaces during its first five years of activity: two furnaces at the crematorium of Hagen in Westphalia in 1926, one at the Weissenfels Crematorium in 1927 and two furnaces at the crematorium of Schwerin in 1930.[607] In the early 1930s, Topf was the leader in the field, while Kori came in last, after Gebrüder Beck, Schneider-Didier and Ruppmann (Hellwig 1931a, p. 370).

11.2. The Coke-Fired Kori Cremation Furnaces for the Concentration Camps

The H. Kori Co. came into its own after the outbreak of the Second World War when the SS decided to set up crematoria in the concentration camps. The firm succeeded in placing its products at many locations, such as Bergen-Belsen, Blechhammer, Dachau, Dora-Mittelbau, Ebensee, Flossenbürg, Gross-Rosen, Lublin-Majdanek, Mauthausen, Natzweiler-Struthof, Neuengamme, Ravensbrück, Sachsenhausen, Stutthof, Trzebinia, Vught, and Westerbork.

11.2.1. The Furnace at the Mauthausen Crematorium

The coke-fired Kori Furnace at *KL* Mauthausen, which went into operation on 4 May 1940 (Photo 247), is probably the first furnace designed by Kori for concentration camps. This furnace is set on a brick platform with its right side placed against the wall of the furnace hall (Photo 236). The front part has the typical double-leaf muffle closure.

The muffle had a grate consisting of three transverse bars and one longitudinal bar in the center, like the grate of the Topf Furnace at Dachau (Photo 239); on the inner left sidewall are three rectangular apertures connected to a channel for the combustion-air feed. In the front part of the furnace, this channel bent downward by 90°, then again by 90° to the horizontal, and let out below the left edge of the muffle door, where it had a butterfly valve (Photos 236f.). A similar valve was also located below the right edge of the muffle door (Photo 236), but the muffle wall on the right had no openings (Photo 242). This air inlet was probably used to supply combustion air to the flue duct for the post-combustion of the unburnt gases.

The ash chamber (Photo 243) was located below the grate and had its door in the front part of the furnace (Photo 236). The gasifier was located in the rear portion of the furnace. The door of the gasifier's loading shaft and the hearth door below it were on the left side of the furnace (Photo 245).

The hearth grate consisted of 14 bars and 2 transverse supporting bars. The loading shaft of the gasifier had an oblique grate of bars at its end, suitable for

---

[607] Verband… 1928, p. 82; *Einäscherungsofen System "Kori" im Krematorium der Stadt Hagen/Westf.* (Document 269); *Einäscherungsofen System "Kori" im Krematorium der Hauptstadt Schwerin* (Document 270), company brochures from the 1930s, APMM, sygn. VI-9a, Vol. 1.

wood use (Photo 246). No service provisions were located in the rear wall of the furnace.

The gas-discharge system consisted of an opening in the vault of the muffle, toward the front, and of a horizontal flue duct, which could be closed by a metal damper (Photo 238).

The corpse-introduction device consisted of a stretcher, guide rollers and the necessary support and blocking frame. We shall come back to this point when we describe the cremation furnaces at the Dachau Camp.

Similar furnaces were set up in the crematoria at *KL* Flossenbürg (Photo 335) and *KL* Ebensee (Photo 336).

11.2.2. The "*Reform-Einäscherungsofen*"

The next model of the Kori Furnaces was an improved version, as it is also expressed in its designation (*Reform-Einäscherungsofen*).

A Kori letter of 18 May 1943, addressed to Office CIII of the *WVHA* contains the following description as part of an offer for this type of furnace (Document 271):[608]

> *"Re: Cremation furnaces*
> *In pursuance of the conversation we had with you concerning the supply of a cremation device of a simplified nature, we propose our coal-fired 'Reform' cremation furnaces, which so far have shown very good results in actual operation. For the project in question, we propose two cremation furnaces, but we suggest ascertaining, in a further discussion, whether these two furnaces will be sufficient for the task. It is also necessary to clarify the positioning of these furnaces, because the fabrication of the fittings and of the anchoring structure depends on this question.– If at all possible, these furnaces must be placed into a closed building and connected to a chimney which may exist at the site. If such a building has already been identified, we beg you to send us a drawing to allow us to propose to you a suitable positioning. From the enclosed drawing, you can gather the space needed for the furnaces with their control station and stoking station. Drawing J.Nr.8998 shows the placement of two furnaces, whereas four furnaces were built for the construction project Dachau shown in Drawing J.Nr.9112. Another drawing with J.Nr.9080 shows the Lublin device with five cremation furnaces and two built-in recuperators.*
> *Concerning the purchase prices for two crematoria* [furnaces]*, we offer the following:*
> *1) 2 'Reform' cremation furnaces of latest design with vaulted coffin chamber and horizontal floor of the ash chamber, including all fittings, doors for introduction, operation and cleaning, air valves, accessories for the main hearth and the post-combustion grate, complete anchoring structure consisting of strong, angled and U-shaped iron bars connected to by anchoring rods, all building materials a first-class standard and specially shaped refractory bricks, refractory mortar, bricks for the front and rear walls, mortar and cement for brickwork as well as complete installation by one of our technicians for combustion devices, while supplying all necessary helpers, each for 4,500 Reichsmarks.*

[608] Letter from H. Kori dated 18 May 1943 to Engineer Waller, at *Amt* C III of *SS-WVHA*. KfSD, 660/41.

If the second furnace is installed together with the first, the price of the second furnace would be reduced to 4,050 Reichsmarks.
This amount, however, does not include loading and shipment costs free on site, nor the traveling cost and expenses for our technician and the daily allowance. We will invoice these expenses separately in a specific list.
Our offer likewise excludes secondary construction work on site, such as earthwork, furnace foundation, construction of the furnaces room as well as the flue ducts to the chimney and the chimney itself.
However, as soon as the arrangement question for the furnace system has been clarified, we will be happy to provide you with a specific offer for building the smoke ducts.
For the introduction of the corpses into the combustion chamber we offer furthermore:

1) 2 cremation carts, concave, with rollers and handles, each at RM 160.-	*RM 320.-*
2) stands with rollers for placement of the introduction cart, each at RM 75.-	*RM 150.-*
	RM 470.-

We guarantee the efficiency of the cremation furnaces supplied, as well as their durability and the supply of the best materials and first-rate labor.
The shipment of the cast-iron fitting and anchoring parts, as well as the specially shaped refractory bricks, can take place at short notice, provided Wehrmacht freight papers are placed at our disposal.
For the shipment of the metal parts of the furnaces we need 1,460 kg per furnace, i.e. 2,920 kg for two furnaces. We enclose the forms for the iron requirements for these parts.
Awaiting your further decisions we salute you

Heil Hitler!
H. Kori Ltd.

Enclosures: 3 drawings – J.Nr.8998, J.Nr.9122, J.Nr.9080 –
Forms for iron requirements."

The *Reform-Einäscherungsofen* was essentially characterized by a positioning of the gasifier on the side of the furnace, a secondary hearth next to it, and an upward flue-gas discharge through the muffle vault. Kori adapted this type to the requirements at the various crematoria, and supplied single furnaces or assembled two, four, or five furnaces in a single brick structure.

The three drawings attached to the above letter are preserved in the Belgrade Archives of the State Commission for Crimes of the Occupiers and Their Collaborators. Our request for the supply of photocopies received no reply. The drawings which we show here (Documents 272f. & 277) are photocopies supplied by the above commission to the Soviets for use at the Nuremberg Trial.[609]

Drawing J.Nr. 8988 (Document 272) is a layout for the crematorium of the New Construction Office at *KL* Neuengamme, with two furnaces connected to the chimney via a common flue.

[609] GARF, 7445-2-125, pp. 89-91.

Drawing J.Nr. 9122 is the design on the basis of which the furnaces in the new crematorium at Dachau were built ("*Baracke X*", Photo 248). These furnaces were structurally the same as those in the Sachsenhausen Crematorium – of which there exist some post-war drawings prepared by the Soviets – but differed from the latter in the design of the flue-gas discharge system. The Soviet drawings and a visit to the site allow us to describe with sufficient accuracy the structure and operation of the *Reform-Einäscherungsöfen* in the various crematoria. The numbers given subsequently in parentheses preceded by the letters "*No.*" refer to the numbers contained in Documents 274-276.

11.2.3. The Furnaces in the Crematorium at the Dachau Camp

The four furnaces are arranged as shown on drawing J.Nr. 9122 (Document 273 and Photo 249). The two central furnaces have a common wall, but their muffles are not directly interconnected. This pair of furnaces is almost identical to the one installed at the Stutthof Crematorium, from which it differs in secondary aspects which we will discuss later. In its front portion, the furnace is designed like the Mauthausen Furnace and similar to the one installed at the Sachsenhausen Camp.

It presents the typical double-leaf introduction door (*Einführungstür*) with the characteristic round openings for viewing and combustion-air feed (65 mm in diameter; Photos 250f.; see *No. 1* in the drawing of the Sachsenhausen Furnace. Documents 274f.; all subsequent numbers refer to these documents). Below it is the ash-chamber door (*Ascheentnahmetür*; *No. 4*) with the rosette-shaped combustion-air inlets (*Luftrosetten*; *No. 5*; Photo 251). These rosettes close the two combustion-air channels (*Luftkanäle*; *No. 6*) set into both side walls of the muffle, leading to the three rectangular apertures in the muffle walls (Photos 253f.; *No. 7*).

The muffle itself (*Einäscherungskammer*; *No. 8*) is 2.20 m long, 0.65 m high and 0.80 m wide. The muffle grate (*Schamotterost*; Photo 268; *No. 9*) consists of 24 transverse refractory T-bars which are flat at the top but arched on the underside, thus forming a flat grate on top and the vault of the ash chamber below, as we can see in Photos 313f.

The gasifier (*Generator*; *No. 11*) is located in the rear portion of the furnace. The gasifier loading door with its two leaves (*Generatorfüllschachtverschluss*; Photo 261; *No. 13*) and the ash-chamber door below (*Feuertür*; *No. 14*; Photo 262) with its air-inlet rosette are positioned on one side wall of the furnace (Photo 257). This rosette (*Luftrosette*; *No. 15*) closes the combustion-air-feed channel (*Luftkanal*; *No. 16*) which enters into the hearth above the hearth grate (*Luftöffnung*; *No. 17*).

The grate of the main hearth (*Hauptfeuerung*) consists of eleven double bars (Photos 263f.) and measures some 80 by 40 cm (*Planrost*; *No. 12*). The grate throughput rate is around 38 kg of coke per hour.

Next to the gasifier is an auxiliary hearth equipped with the ash-chamber door with an air-inlet rosette at the bottom and a single-leaf loading door on top (Photo 260; *Nos. 18f.*) connected to the post-combustion chamber (ash chamber)

via a suitable opening (*No. 20*). We will discuss the connection system of the gasifier and auxiliary hearth to the muffle and post-combustion chamber in the section devoted to the furnaces at Stutthof.

The gases coming from the gasifier enter the muffle and the ash chamber from the rear portion of the furnace (Photo 268), strike the corpse from above and below, and enter the vertical smoke duct, which is located above the forward portion of the muffle (*Rauchkanal*; *No. 21*). The gas-discharge system is shown very clearly in the vertical section of the furnace in Drawing J.Nr. 9122 (Document 273, "*Schnitt* c-d", upper right): the muffle vault, in its front part, has an opening for the gas discharge leading into a smoke duct, which runs above the muffle within the brickwork of that part of the furnace (Photo 257) and then drops down, first vertically then at an angle, past the gasifier within the rear brickwork of the furnace. It finally runs below the floor of the furnace hall and continues horizontally toward the chimney. At the rear of the furnace is a door for cleaning the smoke conduit (Photo 259). Beneath this door, in the floor, is the flue-gas damper (*Rauchkanalschieber*) which moves vertically by means of a metal cable (*Drahtseil*) and rollers (*Rollen*) mounted on the upper portion of the brickwork (Photo 259). The flue-gas channels (*Rauchkanal*) set below the floors of Furnaces 1-2 and 3-4 converge as two conduits which lead, respectively, to the right and left chimney channels, each one of the latter having an internal cross-section of 0.60 m × 0.60 m.

The corpse-introduction system consists of introduction stretchers (*Tragbahren*; Photos 249 & 253f.; *No. 28*) like those used for the Topf and Kori furnaces at Mauthausen, which moves on two rollers (*Rollen*; Photos 252 & 267; *No. 30*) set on a metal stand (*Rollenbock*, No. 31) whose horizontal elements are welded to the frame of the muffle door (Photo 250) with the vertical ones set into the floor (Photo 251). The corpse was placed on the stretcher, the side bars of which moved on the rollers, thus allowing it to be easily introduced into the muffle.

The distinguishing feature of the Kori System was an ingenious system for blocking the corpse in the muffle. This device consisted of a refractory blocking plate (*Schamotteabsperrplatte*) running vertically, like a guillotine, along two guide rails set into the furnace brickwork behind the muffle door (*No. 3*). In the lower part, this plate had a metal frame in the shape which matched the vertical section of the stretcher with its convex upper edge (Photo 266). The plate normally sat in a wrought-iron housing located above the front part of the muffle; it was moved by a metal cable and two pulleys with counterweights (*Gegengewicht*; Photos 255f.). The metal cable ended in a crank. When the plate was not utilized, the crank was held back by means of a hook set into the wall near the muffle door (Photo 265); when it was to be used, after the corpse had been introduced into the muffle, the cable was unhooked, and the plate (in the upper position in Photos 253 and 267) was lowered down to the muffle floor (Photos 265f.). The function of this plate was to retain the corpse in the muffle when the stretcher was withdrawn.

11.2.4. The Furnaces at the Stutthof Crematorium

The Stutthof Crematorium was destroyed, probably by the SS prior to the arrival of the Soviets. The chimney collapsed completely, but the cremation furnaces remained almost unscathed. Photo 270 shows the two coke-fired furnaces as found by the Soviets on their occupation of the camp. At present, the furnaces are located in a building set up after the war (Photo 271). The furnaces are structurally identical to the middle pair of furnaces at the Dachau Crematorium, differing from the latter merely by the absence of blocking plates for retaining the corpse and by a different arrangement of the two rosette valves of the air inlet (next to the muffle doors, instead of being located next to the ash-chamber doors). The refractory brickwork of the muffle shows serious signs of wear (Photos 272 and 274).

For these furnaces we were able to take photos of the way the two hearths are connected to the muffles and ash chambers. Photo 276 shows the two hearths of the right-hand furnace, with the main hearth to the right with the single-leaf door of the ash chamber below, and the double-leaf gasifier loading door above. The secondary hearth is on the left, with its ash-chamber door below and the hearth door above. Photo 277 shows the remains of the hearth grate.

Photo 278 shows the upper portion of the gasifier chamber, which is connected to the ash chamber (lower chamber) and to the muffle (upper chamber). The two chambers are set apart from the refractory grate of the muffle, which appears near the center of the photo, to the left. The upper part of the gasifier chamber ends at the level of the refractory grate of the muffle. Photo 279 shows the muffle as seen from the gasifier outlet. In the upper background, in front of the introduction door, one can see the opening of the vertical conduit for the discharge gases. On the wall to the right, two of the rectangular inlets of the combustion-air feed are visible.

The two auxiliary hearths, one for each furnace, are connected to the respective ash chambers. Photo 280 shows the hearth of the furnace on the left; the upper door is missing. On the inside one can see a broken grate bar, held by a supporting bar. In Photo 281, showing the end of the grate bar in the foreground, one can see the opposite wall of the post-combustion chamber (ash chamber), where we can just perceive, in the lower portion on the right, a part of the ash-chamber floor. Photo 282 shows the post-combustion chamber seen from inside the left-hand auxiliary hearth. The white section appearing in the left-hand corner of the photo is the dislodged end of the grate bar.

The grate of the auxiliary hearth is positioned at the floor level of the post-combustion chamber. It supplied extra heat to the muffle from below through the refractory bars of the muffle grate and also served as a post-combustion grate for those parts of the corpse which had dropped down from the muffle through the bars mentioned. Photo 283 shows the inside of the (destroyed) auxiliary hearth of the furnace on the right. In the background, one can see the opposite wall of the post-combustion chamber with a section of the vault formed by the refractory grate bars. The post-combustion chamber stretches to the right

and left of the auxiliary hearth. Its right-hand portion, seen in Photo 284, is the final portion and is connected to the gasifier chamber.

The outlet of the auxiliary hearth appears on the lower left in Photo 273, which shows the ash/post-combustion chamber of the left-hand furnace. The opening is located at the far end of the floor of the chamber, with the end of the hearth grate bar sticking out at an angle (Photos 280-282). On the left, in the background, one notices the gasifier chamber with the vault formed above by the refractory-grate bars of the muffle grate. Photo 275 shows the ash/post-combustion chamber of the right-hand furnace.

11.2.5. The Furnaces of the Crematorium at Sachsenhausen

The four furnaces of the Sachsenhausen Crematorium (Document 274) were built along the same lines as the Dachau Furnaces, but – as we have mentioned earlier – were equipped with a different layout for the discharge gas. They were grouped together as a single unit 12.46 m long and 2.66 m high (Document 274, A & B). Document 275 shows the horizontal and vertical sections of Furnaces 1 to 3. The gas-discharge system, schematically illustrated in Document 275 (top) and 275a, consisted of a vertical flue channel (*No. 21*) with a right-angle bend above the muffle (*No. 22*) which connected it to another horizontal channel perpendicular to it (*No. 24*) and running within the brickwork above the unit (*No. 25*).

Furnaces 1 through 3 were equipped with a refractory damper set just ahead of the outlet of this channel (Document 274, *Nos. 20a, b, c*); the damper of Furnace 4 was instead placed in the transverse channel, ahead of Furnace 3 (*No. 20d*). This channel was split in two by a central wall (*Nos. 24a & b*): the conduit on the left discharged the fumes coming from Furnaces 1 and 2, the conduit on the right, those of Furnaces 3 and 4. Both channels, via a right-angle bend, fed into two ducts (*Nos. 26a & b*), which each ended up in one of the two ducts (*Nos. 28a & b*) of the chimney (*No. 29*). Only the foundations of these furnaces are left (Photo 337).

11.2.6. The Furnaces of the New Crematorium at Lublin-Majdanek

The crematorium at *KL* Lublin-Majdanek were set on fire by the SS before they left the camp, but the furnaces and the chimney remained intact. The present crematorium building (Photo 285) is a post-war refabrication.[610] Photo 286 shows the furnaces, open to the sky, as they stood at the time of the camp's occupation by the Red Army.

The five furnaces of the Lublin-Majdanek Crematorium (Photo 287) were assembled into a single brick structure, in conformity with the original Drawing J.Nr. 9080 (Document 277), so as to constitute a single cremation plant with five furnaces. A Kori letter of 23 October 1941, addressed to *SS Sturmbannführer* Lenzer, describes the unit as follows:[611]

---

[610] On the crematoria at *KL* Lublin-Majdanek cf.: Graf/Mattogno 2012, pp. 95-116.

[611] Letter from Kori Co. to *SS-Sturmbannführer* Lenzer dated 23 October 1941. APMM, sygn. VI-9a, Vol. 1.

> *"Our drawing, Sheet 2 (J.Nr. 9079), shows the solution of the space issue for a total of 5 cremation furnaces, with Furnace Number 5, in the center, having been conceived as a reserve furnace. Thus, for normal operation, only Furnaces 1-4 have been conceived, and these* [furnaces] *have a common recuperator placed between the two furnaces for utilizing the combustion gases. Each group, constituted by two furnaces with a recuperator, therefore occupies a floor space of 4.80 by 3.00 meters. The introduction doors are in the front portion and below* [them] *there is the access door for the removal of the ashes. At the other side, i.e. in the rear portion of the furnace, we have the hearths, operation of which is effected together from the service or stoking post.*
>
> *At this point, the floor is 0.40 m lower than the floor of the hall, with stone steps placed on the right and left sides of the furnaces. These steps at once also compensate for the difference in height. Above the furnaces is the common flue duct, provided with a by-pass for each one of the 2* [lateral] *cremation furnaces, allowing the feeding of the gases either directly into the chimney or through the recuperator in order to make use of the* [heat in the] *discharge gases. The chimney for one group of furnaces will be built with an open passage 60 by 60 cm and a height of 8-10 meters.*
>
> *In order to be independent of atmospheric conditions which affect the draft of the chimney, a forced-draft device in suction will be installed ahead of the chimney. It will likewise have a by-pass for the off-gas to enable an operation with natural draft as well, if conditions are normal. The flue-gas duct itself which connects the furnaces to the chimney is located below the floor of the hall, as shown by the dotted lines, and can be controlled by means of a flue-gas damper."*

The structure of the plant is illustrated by several technical drawings prepared in August of 1944 by the Polish-Soviet expert commission which investigated it after the occupation of the camp (Documents 278-283, individual portions being indicated, as before, by "*no…*").

The five-muffle cremation plant of *KL* Lublin-Majdanek consisted of two pairs of muffles, one pair on each side, (Document 279, *B, Ofen 1-2 and 3-4*) plus one central furnace (*Ofen 5*). Between the two pairs of the lateral furnaces were two recuperators (*Heizkammer*). Photos 288-294 show, successively, the front of the furnaces and the recuperators, starting from the left-most furnace (No. 1).

The design of the individual furnaces shows some modifications with respect to those at Dachau and Sachsenhausen. In the front part, we have the typical double-leaf introduction door (*Einführungstür*), 0.55 m × 0.65 m in size, with the usual round openings for inspection and air feed (Photo 290; *No. 1*). This muffle door leads into a cremation chamber 0.77 m wide and 0.67 m high (Photos 295-301; *No. 2*), whose floor is made up by a refractory grate (*Schamotterost*) consisting of nine pairs of standard transverse bars (Photo 296; *No. 3*). The effective volume of the muffle is 2.17 cubic meters. The ash chamber (*Aschenraum*) is located below the refractory grate (Photos 313f.; *No. 4*) with a post-combustion grate (*Ausglührost*) in its front part (photos 303f.; *No. 5*). At the front, the ash chamber is closed by two doors (Photo 288): the upper (*Ascheentnahmetür 1*), located immediately below the muffle door (Photo 303;

No. 6), permitted raking, by means of a special tool, the corpse residues which had fallen through the interstices of the refractory grate onto the post-combustion grate, where they would burn out completely; the lower one (*Ascheentnahmetür 2*), located below the former (Photo 304; *No. 7*), was used to remove the ashes of the corpse itself. This door had a rosette vane for feeding air to the post-combustion grate. On the sides of the upper door were two rosette vanes (*Luftrosetten*; Photo 294; *No. 8*) which closed off the two channels feeding combustion air to the muffle (*Lufteintritt*; *No. 9*). These channels (*Luftkanäle*) ran horizontally through the furnace brickwork, then turned upward at a right angle (*No. 10*), bending once again into the horizontal at the level of the muffle, and now ran parallel to it (*No. 11*), feeding air to the muffle through four openings, 8 cm × 8 cm, two on each side (Photos 297-301; *No. 12*).

The gasifier (*Generator*; *No. 13*) was located in the rear portion of the furnace; the hearth (*Feuerung*) consisted of a flat grate (*Planrost*; *No. 14*) 0.68 m × 0.63 m or 0.43 m². The coke throughput rate under natural draft was around 50 kg/hr of coke. The double-leaf loading door of the gasifier (*Generatorfüllschachtverschluss*; Photo 305; *No. 15*) was located in the rear part of the furnace, as was the single-leaf door of the hearth (*Feuertür*; Photo 305; *No. 16*). The gasifier-loading door closed a vaulted opening located in the rear part of the furnace ahead of the refractory grate, as can be seen from Photos 313f. The vaulted top of this opening is also visible from the side of the muffle door (Photos 295 and 301).

The loading shaft of the gasifier had a fire bridge at its upper end, located just below the start of the refractory grate (clearly visible on Photo 313). Beyond the fire bridge the shaft opened up to the vaulted plane of the gasifier neck linking the gasifier to the muffle in such a way that the combustion products leaving the neck struck the refractory grate – and the corpse resting upon it – both from above and below.

The refractory lining of the furnace had a thickness of 12 cm (*Schamottemauerwerk*; *No. 17*). The gas-discharge system was similar to that of the furnaces at *KL* Sachsenhausen except that the muffle, via a vertical conduit (Photo 302; *No. 18*), was linked directly to the horizontal flue duct (*Rauchkanal*; *No. 19*) in the brickwork of the unit (*No. 20*). The latter duct had two cleaning doors at either end (*Reinigungstüren*; Photos 309f.; *No. 21*). This duct contained six refractory dampers (*Rauchkanalschieber*; *Nos. 22a-f*), 0.60 m× 0.45 m in size.

Dampers *a* and *b* controlled the flue-gas flow from Furnaces 1 and 2, respectively. Dampers *c* and *d* belonged to Furnace 5, the center furnace, and allowed the discharge of the flue gas to the right or to the left of both sections. Dampers *e* and *f* controlled the flow from Furnaces 3 and 4. The dampers were balanced by counterweights and moved by metal cables via pulleys suspended from the ceiling beams. The counterweights ran inside two metal rings mounted on the furnace's brickwork next to the rosette vanes for the air, as shown in Photo 289.

Between Furnaces 1-2 and 3-4 two recuperators were located (*Heizkammer*; *No. 23*) consisting of two chambers. Each of the chambers contained a heating coil for the production of hot water (*Heizschlange*; *No. 24*). The coils had an outside area of 15 m² and were linked to two horizontal tubes installed outside

of the chambers, in the rear part of the furnace, through eight vertical tubes of a smaller diameter (Photos 305-308; *No. 25*). Below the second tube was an inspection door (*No. 26*). The two tubes were connected to two boilers located above the recuperator chambers in the manner shown in Drawing J.Nr. 9080 (*Schnitt c-f*, upper right). Such a heat-recovery system for producing hot water had been used by Kori for several decades.[612]

Document 284 shows the design of such a unit for a single recuperator chamber. When all four furnaces were in operation, they could make use of a heating surface of 30 m², with an hourly capacity of 300,000 kilocalories. This was sufficient for 50 shower heads and could accommodate, over an operating period of 20 hours per day, some 5,000 to 6,000 persons in six shifts per hour for an effective showering time of five minutes each.[611]

The discharge gases from Furnaces 1 & 2 (or 5) and 3 & 4 (or 5) passed through the recuperator downward (Document 284, 284a), heating the coil and thus heating water, and then flowed into two underground flue ducts (*Rauchkanäle*; *No. 27*) with a cross-section of 0.70 m × 0.75 m, which led to two draft enhancers in suction (*Saugzuganlagen*; *No. 28*). These devices consisted of a vertical branch (*No. 29*) and an angled branch (*No. 29a*) with a horizontal damper permitting the shutting off of the device; they had a blower (*Gebläse*; *No. 30*) with its electric motor (*No. 31*). The two blowers were each linked to one of the two chimney ducts (*Züge*; *No. 32*) into which the chimney was split (*Schornstein*; *No. 33*). Document 283 shows the flue-gas course for the gases from Furnaces 3 & 4.

The corpse-introduction system consisted of the introduction stretcher with rollers and their stand (Photo 288), but had no corpse blocking plate.

An explanatory sign in five languages, now shown in the reconstructed furnace hall of the crematorium (Photo 317), states:

> *"The crematorium was built in the autumn of 1943. It was heated by coke. The bodies were cremated at a temperature of 700°C. The daily yield was about 1000 bodies."*

This alleged capacity exceeds the actual capacity by a factor of seven.

Contrary to what was asserted by the experts of the Soviet investigative commission, the brickwork of the muffles shows only minor traces of melting of the refractory parts (Photos 297-301); they appear, moreover, only in the vault of the gasifiers. The negligible character of these traces becomes obvious when compared with the obvious appearance of fusion in the gasifier walls of the double-muffle furnace at Gusen (cf. Photo 5), which had been exposed to temperatures of 1,200 to 1,300°C.

Another two *Reform-Einäscherungsöfen* were set up in the crematorium of *KL* Ravensbrück (Photo 338).

---

[612] Cf. Document 266, illustration at the bottom left, which is a "*Verbrennungsanlage mit angeschlossener Warmwasserbereitung*" – incineration device with connected warm-water generation. 11.3. The Oil-Fired Kori Cremation Furnaces for the Concentration Camps

The structure and the operation of the mobile oil-fired Kori cremation furnaces are well described in a drawing by the Krakow "Technical Institute for Heat and Fuel" of the Krakow Mining Academy concerning the furnace at Trzebinia[613] (Photos 330f.), an Auschwitz subcamp. In all probability, the original Kori documents (Document 285)[614] were used for this purpose.

Furnaces of this type were set up at Stutthof (Photos 328f.), Lublin-Majdanek (Photos 318-327), Gross-Rosen (Photos 332-334), Blechhammer (another Auschwitz subcamp; Photo 331a), Bergen-Belsen (Photo 339), Dora-Mittelbau (Photo 340), Natzweiler-Struthof (Photo 341), Neuengamme (two furnaces; Photo 342), Sachsenhausen (two furnaces; Photo 343) and at Vught in Holland (Photo 344).

The subsequently given numbers in parentheses preceded by "*No.*" refer to Document 285a.

The furnace was shaped like a muffle, and on its sides, lined with sheet metal (Photo 318; *No. 10*). At the front, we have the typical double-leaf door (*No. 5*) with the ash-chamber door below (*No. 6*) and the two rosette-type air vanes (*No. 7*) next to it for the air feed to the muffle as in the coke-fired models (Photo 319). The two air channels set inside in the side walls of the muffle were connected to the muffle by three square openings (Photo 320; *No. 2*[615]). The muffle (Photo 320; *No. 1*) was 1.95 m long, 0.60 m high, and 0.70 m wide.

In the rear portion of the muffle was the jet of the main burner (Photo 320; *No. 21*). The muffle grate consisted of twenty refractory bars arranged in two rows and connected in the center (Photo 322; *No. 3*). Below the grate was the post-combustion chamber (ash chamber; *No. 4*) which had the jet of the secondary burner at its far end (Photo 323; *No. 22*). Above the furnace, on the left side, we have the blower (*No. 14*; only the support rack left in Photos 325, 327) with its electric motor (*No. 15*), which fed combustion air to the two burners located at the far end of the furnace (Photo 327; *No. 19*: main burner*; No. 20*: secondary burner) via a system of pipes (*No. 17*).

On the right side of the furnace was the oil tank (*No. 16*), clearly visible on the Stutthof Furnace (Photo 329), from which the fuel was fed to the burners through smaller pipes (*No. 18*). On the lower right-hand side of the furnace was an inspection port for the secondary burner (*n. 8*) and above it, a rosette vane for combustion-air feed to the post-combustion chamber (Photo 326; *No. 7*). The off-gases left the muffle through an opening located in its vault (*No. 11*), in the forward portion of the furnace (Photo 321), and through a short flue duct of wrought iron which rose above the furnace as a small square wrought-iron chimney duct (Photos 324-326) which in turn had a conical wrought-iron shroud bolted onto it (Photos 330f.; *No. 12*; no longer present on the other fur-

---

[613] "Aussenlager Trzebinia" was located near the Trzebionka Hamlet, and therefore it is at times referred to by that name.

[614] *Obozowe krematorium w Trzebionce* (crematorium of the Trzebionka Camp). APMO, no. Neg. 6671.

[615] Only two openings are shown in the Polish drawing.

naces). The shroud was surmounted by the chimney proper, a wrought-iron tube (*No. 13*) as on the Gross-Rosen Furnace (Photo 332). The introduction system consisted of a stand (*No. 24*) with rollers (*No. 25*), as for the coke-fired furnaces.

The cremation furnace installed at *KL* Gross-Rosen (Photo 332), which started operating as early as June of 1941,[616] differed from the other types by the absence of a refractory grate of the muffle, instead of which it had a stretcher in the form of a concave iron grate. The stretcher moved along an iron guide on either side by means of four rollers, likewise made of iron (Photos 333f.), in such a way as to be able to move up to the door of the muffle where the corpse would be introduced.

During the cremation process, the stretcher remained inside the muffle. At present, the furnace is shown without its refractory lining, which was removed at an unknown time (Photo 334).

Document 285 (numbered by me in Document 285a) also shows a schematic drawing of a burner (*No. 25*), manufactured by the Kubitz Co. in Berlin. It consisted of: a jet injecting the combustible mixture (oil sprayed by compressed air; *No. 26*), the combustion-air ducting with its damper (*Luftklappe*; *No. 27*), a control lever (*Regulierhebel*; *No. 28*), the oil-feed tubing (*No. 29*) and its control valve (*Regulierventil*; *No. 30*).

According to professor Dawidowski, the main burner had a feed rate – depending on the control setting – of 4, 6, 9.5, and 13 kg of oil per hour. The secondary burner operated at 1.5, 2.5, and 3.8 kg/hr of oil. Dawidowski's statement, however, that the furnace operated at a temperature of 1,500 to 1,800°C is absolutely unfounded.[617]

Document 286 contains the operating instructions for this type of furnace:[618]

"Operating instructions for the incineration.
<u>Lighting the burners:</u>
A. If the furnace is still warm and the control setting of the burners has not been changed from the previous utilization, no change is necessary, if the fuel is similar.
Lighting is carried out in the following order:
1.) Turn on ventilator
2.) Close damper for burner air
3.) Open on-off valve for oil
4.) Introduce burning wick
5.) Open air damper
As soon as lighting has taken place, close air damper slowly until flame no longer spurts but burns in a stable manner without generation of smoke. If lighting does not take place right away, turn control valve to the left about one quar-

---

[616] Letter from the head of administration of the Gross-Rosen Camp to *Reichsführer*-SS – Inspekteur der Konz.-Lager-Verwaltung-Oranienburg, dated 24 June 1941 on: "ash urns." APMGS, sygn. 2593/DP. Cf. Chapter 12.

[617] AGK, NTN, 145, p. 8, report by Jan Sehn about the Trzebionka camp dated 8 August 1945. This report contains the drawing *Obozowe krematorium w Trzebionce* and various photographs of the ruins of the cremation furnace.

[618] "Betriebsvorschrift für die Einäscherung." ROD, C[64]392.

ter turn with the vertical control lever, then, when burner lights up, turn it slowly to the right again. When the furnace has warmed, try feeding more air by opening the air damper. After 5 minutes, open the air rosette on the furnace by about 3 centimeters.
B. If the furnace is cold, or if the control setting of the burners has been changed, control of the burners must be done as follows:
1.) Raise cross stroke by about one half
2.) Turn on blower
3.) Close air feed to burner
4.) Set control lever to an upright position
5.) Open upper control valve by about 2 turns, lower control valve by about one and one-half turns
6.) Introduce burning wick
7.) Open oil on-off valve
8.) Close air damper completely.
If lighting does not take place immediately, open control valve a little more. A few minutes after lighting, close it until flame burns well. If flame smokes, raise cross stroke a little toward 'closed' position. Once the burner has been in operation for a few minutes, the control lever must be turned all the way to the right. If the flame burns well, link control lever to control valve.
If needed, control once more by raising if smoke forms in case of large-scale production [cremation]. *If flame goes off and on again intermittently (sputtering), there is too much air. In that case, close air damper until flame burns steadily. When the furnace has warmed up, the air vane may be opened. After 5 minutes, open air rosette vane of furnace air by about 3 centimeters."*

11.4. The Oil-Fired Cremation Furnaces Built by Ignis-Hüttenbau A.G. at the Terezín Crematorium

In the course of 1942, at Terezín, then called Theresienstadt, a crematorium was built for the ghetto's populace. On 10 October 1941, during a meeting on the subject of establishing the ghetto, the governing proposal had already been defined in the following terms:[619]

"The Jews must not, in any case, be buried, but it is instead necessary to carry out a local cremation within the ghetto on the smallest scale possible, not accessible to the public."

On the construction of the crematorium, a detailed cost estimate exists which was made on 2 April 1942 by the firm Ignis-Hüttenbau A.G. of Teplitz-Schönau, now Teplice in the Czech Republic, most parts of which at the time belonged to the German Protectorate of Bohemia and Moravia.

I will translate here merely the part which concerns the cremation devices:[620]

---

[619] "*Notizen aus der Besprechung am 10.10.41 über die Lösung der Judenfrage*," German text in Kryl 1983, p. 41.

[620] Letter and cost estimate from Ignis-Hüttenbau A.G. of Teplitz-Schönau dated 2 April 1942 "*An die Zentralstelle für jüdische Auswanderer, z.Hd. des Kommandos der Waffen-SS in Theresienstadt*" concerning "*Errichtung eines Krematoriums in Theresienstadt*." PT, A 7-856.

"Based on the delivery conditions as set out below, as well as on Drawing No. 10986, we offer you a gas- or oil-fired cremation furnace as follows:
Our supply includes:
a) the supply of all refractory bricks and insulating materials for a weight of 18,000 kilograms;
b) the supply of the complete anchoring system of the furnace made of steel, as well as the cast-iron doors, the door panels[621] *and various parts of the furnace, with the iron damper and its handling device, as well as the supply of an introduction cart, with its rail, a hand-winch including the cable for the handling of the furnace door, for a weight of about 3,000 kilograms;*
c) the supply of a blower for the combustion air with an output of about 8 m³ per minute, 400 mm water column, including a motor of about 2 hp, as well as the supply of an exhaust device for removing the flue gases with an output of 60 m³ per minute and a motor 3 hp, including the supply of the ducting and smaller tubing[622] *for the furnace, as well as the fittings for the air-control valves for a weight of about 950 kilograms:*
d) the oil or gas burners with their controls, for a weight of about 50 kilograms;
e) the instrument panel about 800 by 800 mm in size, including temperature indicator, switch, and two thermocouples, as well as dynamometer, for a weight of about 60 kilograms;
f) the complete construction of the furnace as well as the mounting of the metal parts by our technicians.
On the basis of the above conditions, the price of a complete oil-fired furnace, complete with oil tank 600 mm in diameter and 900 mm high and its preheater, electrical heating cartridge and fittings, excluding shipment, excluding loading, with assistants supplied, without wood supply for drying in the furnace, with start-up and training of operators, amounts to 15,200 Reichsmarks.
The price of the furnace does not include the flue-gas conduit up to the chimney, nor lighting and water for the construction, but includes the supply of all scaffolding.
The weight needed for the supply [of metal] *for the gas-fired furnace is 4,600 kg of iron materials.*
For the consumption of gas, we attach Sheet 1741.
The consumption of gas thus depends essentially on the number of cremations.

Delivery time.
Delivery time for the oil-fired furnace is presently – for a case of maximum urgency – about 8-10 weeks after receipt of the iron.

Warranty.
As shown on Sheet 1741, consumption of oil or gas depends on the number of cremations. In the case of continuous operation, day and night, the furnace can carry out 15-20 cremations in 24 hours, and for the number of cremations mentioned, oil or gas consumption is minimal and thus insignificant.
In the case of an uninterrupted operation and with 250 cremations per year, oil consumption is about 5 kg per cremation, if cremations are carried out every 10 days.

---

621 *I.e.* the doors of the muffle itself.
622 Read "*Leitungen*" instead of a meaningless "*Leistungen*" in the German original.

Normal duration of a cremation is 1-1.5 hours, preheating time of the furnace from a cold state is around 3 hours, from a warm state around 1 hour.
The furnace in this specific case has been chosen to have the simplest possible structure, and no effort has been made to present a particularly attractive construction or cladding. It does, however, fulfill completely all conditions regarding its construction or its appearance."

On account of a rapid increase in mortality registered at the Theresienstadt Ghetto – from 256 deaths in April of 1942 to 2,327 in May and 3,941 in June (Terezínská Iniziativa 1995, vol. I, p. 33) – the crematorium was eventually equipped with four furnaces of the type described in the cost estimate.

The furnaces, each one 1.60 m high (front), 1.90 m wide and 3.40 m long, were set up in the four corners of the furnace hall and formed two pairs of mirror images as shown in Photos 345, 345a.

In the front portion of the furnaces was the muffle door with its two leaves (100 cm × 90 cm) which was at the level of the pavement to allow manipulation of the low cart for the introduction of the coffin (Photo 346). Behind this door was a refractory closure (*Türplatte*) which ran vertically along two guide bars set into the furnace brickwork and which allowed closing the mouth of the muffle completely (Photos 346 and 359). The muffle was 100 cm high, 90 cm wide and 2.60 m long.

At the rear portion of the furnaces (Photo 348) was the service area on a lower level that could be accessed via five steps. At that part of the furnace were installed, from top to bottom, the oil burner, the inlet for the removal of the cremation residues, the door of the post-combustion chamber, and the door of the ash compartment.

Two metal tubes fed into the burner, one for the fuel (smaller section), and the other for the combustion air (larger section). Each pair of furnaces had an oil tank set on a metal stand attached to the upper portion of the right-hand wall of the cremation hall, as shown in Photo 345. From each tank, a tube went down along the wall and then branched out into two tubes: one continued along the wall and went to the furnace nearest the wall, the other ran horizontally through the furnace hall up to the opposite wall and fed the furnace located there. Both tubes, before reaching their respective burner, passed through an oil preheater located on a stand between the furnace and the wall (Photo 349).

The combustion-air tube passed beneath the floor and went to a blower set into the service pit along the wall flanking the furnace (cf. Photos 356 and 358). Re-emerging from the floor near the furnace, this tube ran vertically along the rear wall of the furnace, then turned at a right angle and ran horizontally along the upper part of the furnace, made another right-angle turn and ran down vertically. From both vertical portions which ran along the two edges of the furnace, eight parallel pipes of smaller diameter left towards the outside and one towards the inside (cf. Photo 348).

The sixteen outer tubes, each with a valve for control of the air flow, bent at a right angle and ran along the sidewall of the furnace (Photo 347). Each tube went through the brickwork of the furnace at a certain interval from the others, and was connected to a jet inside the muffle. The two inner tubes went through

the brickwork at the rear of the furnace and emerged from the rear wall of the furnace as two lateral jets located between the burner and the door for the removal of the cremation residues. This air-feed system was copied from the Volckmann-Ludwig Furnace, as was the elliptical vault of the muffle (cf. Photo 352) and the muffle floor, which was not a grate but a solid refractory plate (Photo 353).

In the front part of the furnace, the floor was level with the introduction door; at the rear, on the other hand, it ended in front of the door for the removal of the combustion ash in a kind of deep step, and the resulting space constituted the post-combustion chamber. The floor of this chamber, in turn, ended in something like a step, ahead of the rear wall of the furnace, thus creating the space of the ash chamber itself. The ash chamber held a movable sheet-metal box (Photos 351 and 355).

The corpse-introduction device consisted of a metal cart running on rails (Photo 361). The muffle door was moved by a hand winch with metal cable, counterweight and pulley (Photo 360). The corpses were burned in lightweight coffins of rough wooden boards (Photos 361a, 362).

The crematorium had two chimneys running along the side walls of the furnace hall as shown in Photo 345a. Each chimney had its forced-draft device with a blower with an output of 60 m³ of smoke per minute set up at its base. The device positioned at the base of the chimney on the left (adjacent to the main door of the crematorium) served the first pair of furnaces (the pair situated near the main entrance), while the device at the base of the chimney on the right was connected to the second pair (the one near the rear door of the crematorium).

According to the supplier, if the furnace was operated properly, each furnace would have permitted 15 to 20 cremations in 24 hours. However, the crematorium personnel had devised an operating procedure which, while being illegal, allowed reaching a maximum capacity with a minimum of fuel consumption. This practice was made possible by the unusual length of the muffle and ran as follows:

After preheating, the first corpse was introduced into the furnace. The coffin was placed in the front part of the muffle, where it was struck by the combustion air coming from the eight air jets located there, and it burned rapidly. At that time, drying of the corpse began. When, after something like 30 to 35 minutes, the desiccation process had reached an advanced stage or had come to an end, the desiccated and dismembered corpse would be pulled into the rear portion of the furnace close to the burner by means of a 4-m-long rake (clearly showing in Photo 349) introduced from the opening at the far end of the furnace, and the main combustion phase took place in that area of the furnace. Here, the corpse was directly exposed to the adjustable flame of the burner and to the combustion air coming from the ten air jets located there. When the main combustion was complete, the corpse residues were raked down into the post-combustion chamber, where they burned out, and then, reaching through the door of the post-combustion chamber, the operator raked the ashes into the ash chamber, where they cooled down.

Operating in this manner continuously, there were two corpses in the furnace at any given time, one in the drying phase, and the other in the combustion phase. Hence the duration of the cremation generally coincided with the time taken by the desiccation of a corpse.

From the point of view of heat management, the heat generated by the combustion of the corpse in the rear part of the muffle was partly used for the desiccation of the corpse in the forward section, with a considerable portion of the heat needed for this being contributed by the coffin's combustion. This reduced fuel consumption even further.

The operating results of the Terezín Furnace demonstrate the great efficiency of such a procedure. In Appendix 1.2., I present a statistical analysis of a part of the cremation lists recorded for this crematorium. This analysis is based on a sample of 717 cremations carried out between 3 October and 15 November 1943 on 41 operating days. In addition to the table showing the summary of my results (Table 1, App. 1.2.), I also present 11 tables with all original documents (cf. Documents 289f.), except for the names of the persons cremated, for whom I only mention the gender. For reasons of space, the tables refer only to days on which at least 24 cremations were carried out. Document 289 shows the manner in which the lists of cremations in the Terezín Crematorium were kept.

The minimum average duration of cremations on any single day was about 32 minutes in Furnace No. III (9 November 1943, with 23 cremations) and 31 minutes in Furnace No. IV (on 10 October 1943, with 17 cremations). The average duration of a cremation was about 36 minutes for both furnaces.[623]

For the 682 cremations where the duration is indicated,[624] a total of 491, or some 72%, took 35 minutes or less, 148 cases, or about 22%, took between 35 and 45 minutes, 42 lasted between 45+ and 60 minutes, and one cremation took longer than 60 minutes, as shown in the following table:[625]

Table 19: Duration of Cremations at the Terezín Crematorium

DURATION [MIN]	MALES	FEMALES	DURATION [MIN]	MALES	FEMALES
15	1	0	45	26	16
25	3	5	50	12	26
30	59	114	55	1	0
35	146	163	60	2	1
40	57	49	70	1	0
			Total	308	374

The average duration of a cremation of a female corpse was around 35 minutes, that of a male corpse 36½ minutes. Each furnace, hence, was usually able to cremate 40 corpses in 24 hours, with highs of around 45 to 46 corpses.

---

[623] I have left out the data concerning Furnace II because only 22 cremations took place there.

[624] At times, the documents give only the time of the beginning of the last cremation but not that of its completion.

[625] Two cremations, on 7 October 1943, had an exceptionally long duration (one and a quarter hours and three and a quarter hours) because of a failure of the electric power supply.

In order to save fuel, cremations were carried out in a single furnace which, in this manner, would always stay warm. After a certain number of cremations, another furnace would be used, and so on, in a rotating cycle of operations.

The crematorium staff normally worked two shifts, one from 6 AM to 1 PM, the other from 1 PM to 8 PM (cf. Document 290).

Over the 41 days of activity analyzed here, Furnace No. II was used twice (22 cremations), Furnace No. III 17 times (298 cremations), Furnace No. IV 22 times (397 cremations). Overall, there were nine cycles with up to ten cremations, 16 cycles involving between 11 and 20 cremations, 16 cycles of more than 20 cremations, up to a maximum of 27.

11.5. The Didier Cremation Furnaces for Concentration Camps

The Berlin company Didier-Werke AG likewise built cremation furnaces for the concentration camps. A letter from this company addressed to a certain Boriwoje Palitsch in Belgrade on 25 August 1943 contains the following offer (Document 287):[626]

"Cremation unit for SS at Belgrade

With reference to the visit of your esteemed son and to the meeting our section manager Storl had with him, we take note of the fact that the SS unit at Belgrade intends to build a cremation plant for a rather-large concentration camp and that you have been requested to design and build the plant, together with an architect stationed there.

As you have no experience with furnace construction, you would like to obtain the necessary drawings.

We declare to be ready to execute the drawing of the furnace with its anchoring system and the drawings of the fittings limited to this particular case exclusively. The corresponding costs would be 600 RM,

payable one half with the confirmation of the order and one half on notification that the drawings have been completed.

In the design of the furnace, we have paid particular attention to the fact that the inner structure can be built with normal refractory bricks, avoiding the use of bricks of special shape, in order to enable a rapid erection of the unit. The metal parts will be designed with this point in mind as well.

For the introduction of the corpses into the furnace, we propose a simple fork made of tubing, running on two rollers.

The furnaces will each have a cremation chamber only 600 mm wide and 450 mm high, because coffins are not intended to be used.

For the transportation of the corpses from the holding location to the furnaces we recommend using a transfer cart and will provide you with a sketch also giving the dimensions for this device.

The chimney necessary for the operation of the furnaces must have an open cross-sectional area 500 by 500 mm and must be built to a height of 14-16 meters. If, for special reasons, such a chimney cannot be built, it will be necessary to install a draft enhancer in suction between the furnace and the chimney.

---

[626] Letter from Didier-Werke AG to Boriwoje Palitsch dated 25 August 1943. Document USSR-64.

As the furnaces operate at elevated temperatures, the wall of the combustion chamber must not be too thin in order to avoid excessive heat loss by radiation. For this reason, the furnaces must have an outside width of about 2,000 millimeters. For the same reason, we have suitably altered the building project which has been supplied to us and send you a sketch No. 0913, on which we have indicated the minimum dimensions needed.

In order to enable you to draw up a preliminary estimate as soon as possible, please note that the requirements for one furnace are:

1,100 kg vault bricks, Seger Cone No. 33
5,500 kg normal bricks, Seger Cone No. 33
1,000 kg fireclay mortar
5,000 pieces ordinary bricks for the outer brickwork of the furnace
100 kg lime
3.6 m³ sand
2 m³ argillaceous earth

For the steel parts:

500 kg iron for anchoring
60 kg round anchor bars
85 kg muffle-door frame with counterweights and cable pulley
40 kg smoke-duct damper frame with counterweights and cable pulley
25 kg 2 air inlets
200 kg one hearth, slag-removal and ash-removal door each[627]
25 kg pokers
10 kg 2 ash boxes
160 kg cast-iron bars of the grate
60 kg supporting bars of the grate.

One must add the same quantities for the second furnace and the building material for the flue duct and the chimney. The flue duct as well as the lower part of the chimney up to a height of 3-4 m must be lined with refractory bricks. For this purpose, however, a lower grade may be used.

The hearth of the furnaces will be designed in such a way that besides coke, coal or wood may be used as well.

Respectfully yours
Didier-Werke A.G."

Drawing No. 0913 (Document 288),[628] prepared by Didier-Werke on 23 August 1943, shows two cremation furnaces 2,000 mm × 2,000 mm × 2,800 mm (length) with introduction doors running vertically and manipulated by means of a metal cable and two pulleys, suspended from the ceiling, and balanced by a counterweight next to the furnace. The furnaces are connected to a chimney with an internal open cross-sectional area of 500 mm × 500 mm and a height of 16 meters.

[627] This weight is too high by comparison and obviously in error.
[628] GARF, 7445-2-125, p. 92.

11.6. Comparison of the Designs by Kori, Ignis-Hüttenbau, Didier and Topf

The coke-fired Kori Furnaces are more massive than the multi-muffle Topf furnaces. A single-muffle Kori Furnace has, in fact, a volume more or less the same as a double-muffle Topf Furnace. One must assume that the refractory brickwork of the furnace was heavier as well. A comparison with the Didier single-mufle furnace – with its refractory brickwork of 7,600 kg – shows in any case that the Topf Furnaces with two, three and four muffles had a very lightweight brickwork: some 10,000 kg for the double-muffle furnace, 10,500 kg for the triple-muffle furnace, and some 12,000 kg for the four-muffle furnace; or per muffle: 5,000 kg for the double-, 3,500 kg for the triple-, and 3,000 kg for the four-muffle furnace (including their share of the generators). This led to a greater heat loss by radiation and a shorter service life of these Topf Furnaces.

The Kori Furnaces, furthermore, had a much more-advantageous arrangement of the gasifier and the flue duct as far as heat economy is concerned, but the Topf triple- and eight-muffle furnaces had a lower fuel consumption.

Another very positive feature of the multi-muffle Topf Furnaces was their decidedly more-competitive price: While a single Kori Furnace, without extras, would cost 4,500 RM in 1943, a triple-muffle Topf Furnace, without extras, sold for 6,378 RM in 1941, or 2,126 RM per muffle; an eight-muffle furnace, in 1941, was priced at only 13,800 RM, including the introduction device, or barely 1,725 RM for one muffle.

Kori had offered to reduce the price from 4,500 to 4,050 RM for the second furnace if two furnaces were built side-by-side, thus having a common central wall, like the two central furnaces at the Dachau Crematorium or the two furnaces at Stutthof. An even larger price reduction was offered if several furnaces were grouped in a single brick structure, like the furnace with four muffles at *KL* Sachsenhausen or the five-muffle furnace at Lublin-Majdanek. But it seems that they never went so far as to design a furnace with several interlinked muffles such as the Topf Furnaces with two, three or eight muffles.

In my opinion, Kori felt that their design was more profitable, even though the Topf multi-muffle furnaces were not protected by any patents. Actually, their designer, Engineer Kurt Prüfer, had simply taken over and adapted an idea which had been around since the end of the preceding century with respect to collective crematoria (cf. Unit I, Chapter 10).

The Ignis-Hüttenbau Furnaces set up at the Terezín Crematorium cannot be compared directly to the Topf Furnaces, because of their different design and on account of the fuel used. As explained earlier, these furnaces were much more like civilian furnaces, especially in the case of the Volckmann-Ludwig types, than like furnaces designed for concentration camps. For that reason, the operating performances of these furnaces are unique. Cremation procedures such as those performed normally at the Terezín Crematorium could not have been replicated in any of the coke-fired furnaces built by Topf, Kori or Didier.

Even though the operating instructions for the double- and triple-muffle Topf Furnaces allowed for the simultaneous presence of two corpses in one fur-

nace, they were in separate chambers and in different stages of cremation: One corpse was in the final phase of post-combustion in the ash chamber, while the other, located in the muffle, was in the early stages of the drying phase. For that reason, the time for which the two cremations overlapped was actually the period of post-combustion (some 20 minutes), and the average duration of the cremation process was therefore the time needed to reach the high point of the main combustion in the muffle (about one hour).

As against this, the management of the Ignis-Hüttenbau Furnaces allowed the simultaneous presence of two corpses in the same chamber (muffle), the first one in the combustion phase and the second one in the desiccation phase. Hence the time for which the two overlapped was the total time needed for the combustion and the post-combustion, and the actual cremation time thus corresponded to the duration of the desiccation.

It is obvious that such a mode of operation was impossible in Topf Furnaces, because the muffle was too short to allow placing two corpses, one behind the other, and because the grate operated vertically: the muffle was free for the introduction of a fresh corpse only when the remains of the previous corpse had dropped into the ash chamber through the openings in the grate, which occurred only after the high point of the main combustion. The floor of the Ignis-Hüttenbau Furnaces, because of its unusual length, operated in a horizontal fashion instead.

To carry out such a procedure in a furnace with a grate operating vertically it would have been necessary to use a device such as the one designed by Martin Klettner. Here, the muffle no longer is a cremation chamber, but a drying chamber, whereas the post-combustion chamber becomes the combustion chamber as such. The muffle grate consists of only two supporting bars for the coffin, set apart widely at some 40 cm, and 65 and 50 cm from the start of the inclined plane on either side.

The inventor proposed that the corpse, once the coffin has burned, will first of all dry out and fall apart in the muffle in such a manner that its combustible parts, still having an appreciable mass, fall into the combustion chamber where they will then burn actively. If, at that point, another corpse is introduced into the muffle, the furnace will contain two corpses concurrently, one in the drying phase and one in the combustion phase, exactly as in the crematorium at Terezín, and that explains the extremely short duration of cremations undertaken in the Martin Klettner Furnace (cf. Document 137).

The results of the operation of the Terezín Crematorium indirectly confirm our conclusions concerning the cremation of several corpses in one muffle (cf. Subchapter 9.2.), because they demonstrate that the simultaneous cremation of two corpses in one furnace (with a staggered way of introduction), while being possible, required a design and a heating system different from what was used for the Topf Furnaces, in which such an operation would not have been technically feasible.

12. The Topf Furnaces and Regulations on Cremations in Greater Germany at the Outset of World War II

When the first concentration camps were set up in Germany, the SS did not even have the slightest notion of the high level of mortality which would strike these camps in later years and, for that reason, they never worried about cremating, within the camps, the corpses of any detainees who died there. Initially they simply let nearby civilian crematoria take care of these matters, and only when, against all expectations, mortality began to get out of hand, they decided to build crematoria within the camps themselves.

Originally, the Buchenwald Camp used the State Crematorium at Weimar for this purpose.[629] Between 5 September 1938 and 3 May 1940, the corpses of detainees who had died at the Mauthausen Camp were sent to the Municipal Crematorium at Steyr.[630] At least until December of 1941, the Wewelsburg Camp relied on the Bielefeld Crematorium (cf. Document 86), while the PoW/labor camp at Gross-Rosen used the Liegnitz Municipal Crematorium.[631] Even the Auschwitz Camp, in its early days, sent its deceased to the civilian crematorium of Gleiwitz (today Gliwice; Piper 1994, p. 158).

When the first crematoria began to be set up in concentration camps later on, they were subject to strict regulations, perfectly complying with current legislation applying to civilian crematoria. In this respect, Himmler's "Decree concerning the execution of cremations in the Sachsenhausen Concentration Camp," promulgated on 28 February 1940, is of particular importance, hence I present the translation of the entire text:[632]

"C o p y

The Reichsführer SS
and Head of the German police
IV – 509/40g

Berlin, 28 February 1940

Decree concerning the execution of cremations in the Sachsenhausen Concentration Camp.

I. General principles
(1) The detainees deceased in the camp will, in principle, be cremated in the local [i.e. in the camp] *crematorium.*
Only in exceptional cases and with the approval of the Head of the Security Police and the Security Service may the corpse be handed over to relatives for burial.
At times (e.g. in times of war) when the handing over of corpses to relatives for the purpose of transfer to the country of origin is prohibited, all deceased detainees will be cremated in the camp crematorium.

---

629 NO-4353. Letter from *Bauleitung* of *KL* Buchenwald to *SS-Gruppenführer* Eicke dated 18 June 1938.
630 ÖDMM, Archiv, 7, 4.
631 Czuj/Kempisty 1977. During that time, the corpses of 3,591 detainees from that camp were incinerated at the crematorium at Liegnitz (p. 113). The article is based on the *Einäscherungslisten* (incineration lists) of this crematorium.
632 "*Erlass über die Durchführung von Einäscherungen im Krematorium des Konzentrationslagers Sachsenhausen*." BAK, NS 3/425.

II. Official certificate by the camp physician, autopsy, release by public prosecutor.
(1) After each case of death, the camp physician must establish an official certificate on the cause of death.
(2) In cases of violent death (e.g. an accident causing immediate death or death after a longer period of illness, suicide, death by shooting during an escape) the camp physician, together with another SS physician, must carry out an autopsy of the corpse and establish, in the usual manner, a detailed report on the results of the autopsy.
(3) An SS Führer, appointed by the camp commandant, must be present at the autopsy and countersign the report. The SS Führer appointed to participate in the autopsy must be appointed in advance, for a considerable period and for all cases which may occur.
(4) Furthermore, in cases of violent death, the competent public prosecutor must be informed immediately. The camp commandant may issue the incineration order (IV,4) only after the receipt of the release notice from the public prosecutor.

III. Notification of relatives.
(1) In all cases of death, the camp commandant must immediately notify the relatives of the deceased detainee by telegraph, if the address of the relatives is known at the camp.
(2) If the address is not known, the camp will get in touch as quickly as possible with the (directing) office of the State Police which ordered the internment of the deceased. The (directing) offices of the State Police are charged to forward the notification without delay.
(3) If (e.g. during war) it is not possible to hand the corpse as such over to the relatives, they must be informed in the notification that the deceased will be cremated. At the same time, they must be informed – unless particular reasons forbid this – that, at their request – to be expressed telegraphically within 24 hours – they will be given the possibility, up to a certain point in time, to view the detainee in the camp one last time.
(4) The permissible time span given to the relatives for a possible last visit of the deceased must be set in such a way that the relatives have enough time to travel to the camp. As a rule, the time span must not exceed 3 days.

IV. Operating rules for the crematorium at the Sachsenhausen Camp.

1.

Responsible head.

(1) The camp commandant is responsible for the management of the crematorium and for the execution of the cremation in accordance with the rules.
(2) He must designate a crematorium head immediately responsible and subordinated to him. The latter may receive orders only from the camp commandant. If the orders of the camp commandant violate the provisions of this decree, he must so inform the camp commandant.
If necessary, a decision from the Inspector of the Concentration Camps must be requested.
For fundamental questions, the decision of the Head of the Security Police and the Security Service must be requested.

2.

Keeping of the list

(1) The camp commandant must maintain a special death register of the deceased detainees to be cremated. In this list, each deceased detainee must be assigned a consecutive registration number. Furthermore, the list must mention his [family] *name and first name, ID number, place and date of birth, last residence, profession, brief mention of reasons of internment, date and cause of death.*

(2) This registration number must appear on the other documents (official medical certificate, autopsy report, cremation order of camp commandant).

3.

Corpse handling

(1) The corpses must be taken to the morgue of the crematorium and be arranged there in such a way as to be able to be possibly viewed there by the relatives.

(2) The corpses must be lodged in wooden coffins. The coffins must not have any incombustible metallic decorations, handles etc., and must be of a size and a kind so as not to impose difficulties for the subsequent cremation. No pitch may be used for filling out any joints.

(3) At the head of the coffin must be attached a metal tag with the embossed or imprinted number of the death register (cf. 2).

(4) Any objects of value still present (e.g. rings) must be removed from the corpse and handed over to the relatives together with other things left [by the dead person]*, against receipt.*

(5) Special legal dispositions apply for the treatment of detainees who may have died of an infectious disease. Any measures necessary in such cases (e.g. prohibition of opening the coffin and possibly prohibition of visits by relatives) must be decided by the camp physician.

4.

Cremation

(1) The cremation may take place only after [issuance of] *the order of the camp commandant. The camp commandant may give this order only after an official medical death certificate and/or possibly an autopsy report have been issued and after the relatives have viewed the deceased or after the permissible time span for such a visit has elapsed, as the case may be.*

(2) The camp commandant must give the cremation order in writing, and this order, together with the official medical death certificate or autopsy report, and with the release notice by the public prosecutor in the case of violent death, and possibly with the police dispositions on the part of the camp physician (which may exclude visitation by the relatives) must be transmitted to the head of the crematorium.

(3) The head of the crematorium may undertake the incineration only after these documents have been received.

(4) The cremation must take place not later than 24 hours after the cremation order has been issued. If this time limit cannot be maintained, the head of the crematorium must request an extension and give the reason for the delay.

(5) In one incineration chamber only one corpse may be incinerated at one time.

(6) Before the introduction of the corpse, the cremation furnace must be heated until the walls of the [cremation] *chamber are glowing, so that the incineration*

process may take place without further or supplemental heating. Only in exceptional cases may additional heat be provided during the incineration process.
(7) During the incineration process, care must be taken so that, if at all possible, no smoke escapes from the chimney.
(8) The observation of the incineration itself is not permitted either to the relatives or to any third persons, but only to the employees of the crematorium. In special cases, the camp commandant may personally issue permission to individual persons to view the process, if such permission is required for special reasons.
(9) After the end of a cremation, the incineration chamber must be thoroughly cleaned.

5.

Treatment of the ashes

(1) After the cremation, the ashes must be removed from the furnace, cooled, freed by means of magnets of any metallic parts and then collected together with the identification tag in a strong and durable container, air- and water-tight, and then closed. The ashes of each corpse must be collected in a separate ash container. The lid of the container must be made of durable material as well. A durable metal tag attached to the container must contain the following data:
1) Cremation sequence number agreeing with the cremation register (cf. No. 6) and with the numerical tag [placed at the head of the coffin]*,*
2) Last name and first name
3) Date and place of birth
4) Date of death
5) Day of cremation.
(2) The containers are to be in conformity with DIN Standard 3198 'Ash Capsules for Urns' set by the German Standards Institute in Berlin.

6.

Register of cremations

(1) For the cremations performed, a register must be kept by the personnel containing the same data as the corresponding list of deaths concerning the corpses taken to the crematorium kept by the command in accordance with Item 2.). Here, however, mention must also be made of the day of the cremation and of the administration of the cemetery to which the ashes have been sent. The register must be closed at the end of each calendar year and must be checked against the book kept by the administration.[633] *This counter-check and the agreement must be certified in the closing note.*

7.

Interment of the ashes.

(1) The ashes, if at all possible, must not be interred in the camp cemetery or in the Municipal Cemetery of Sachsenhausen, but shall – if no particular reasons speak against it in the case in question – in principle be sent to the place of residence of the relatives to allow them [i.e. the ashes] *to be interred in the local cemetery.*
(2) Before shipping the ashes of a prominent detainee, the decision of the Head of the Security Police and the Security Service must be awaited.

633 The word *Verwaltung* (administration) is struck out and replaced by the handwritten entry *Polit. Abteilung* (Political Department).

(3) In case the interment of the urns in the local cemetery of the relatives presents any difficulties, the relatives must be requested to indicate the cemetery to which the ash container is to be sent.
(4) The ashes must not remain in the possession of the relatives, even temporarily. Therefore, they or their appointees must not be given custody of the container, not even for interment at some other location. The ashes must rather be sent to the administration of the cemetery where interment is to take place.
(5) If no relatives of the deceased exist, it should be verified whether the interment of the ashes in the cemetery of the last place of residence does not present any difficulty. If interment is possible there, the ashes are to be sent to the administration of that cemetery.
In all cases where the shipment to the administration of the cemetery at the last place of residence is not advisable, the ashes must be transferred to one of the cemeteries of Greater Berlin after notification to the municipal administration of the Reich capital Berlin. In doing so, care must be taken to the effect that the urns are distributed evenly throughout all cemeteries concerned in the Greater Berlin area.
(6) Shipment of the ashes is to be made, in principle, at the expenses of the relatives.
(7) If the relatives are not in a position to bear such expenses, it is necessary to request reimbursement of the costs by the competent local aid association. Cremation fees must not be charged to the relatives.

8.

Final report.

(1) After the execution of the cremation and shipment of the ashes, the head of the crematorium must transmit to the camp commandant a final report.
(2) The official medical certificates, the reports on the autopsy, the release notice from the public prosecutor and similar documents sent together with the cremation order must remain in the crematorium office.

V. Exceptions
(1) In individual cases, the Reichsführer-SS *and Head of the German Police may order deviations from the above provisions.*

VI. Supervision.
(1) Once a year routine scheduled inspection and once a year an unannounced inspection of the crematorium service must take place. The performance of these inspections is under the authority of the Inspector of Concentration Camps then in charge. A report on the individual inspections and their results must be presented to the Reichsführer-SS. *A copy of this report must be sent to the Head of the Security Police and the Security Service.*

SS Untersturmführer."

The close similarity of this text to the "Operating regulations for cremation equipment" of 5 November 1935 is obvious (see p. 127). There is reason to believe that, at least within Greater Germany, such regulations remained in force up to the end of the war.

On 17 October 1942, *SS Obersturmbannführer* Liebehenschel, head of Office Group D at the *WVHA,* sent to all commandants of concentration camps a circular entitled "Advice to relatives of detainees deceased in concentration camps" in which he stated with reference to Himmler's above-mentioned decree:[634]

> *"Several camp commandants have requested to prohibit viewing of the corpses by relatives during the summer months for hygienic reasons. After consultations with the RSHA, you are informed that a change in the RFSS decree is not possible at the moment."*

Fritz Sander's patent application of 26 October 1942 tells us that the "Law on cremations" of 15 May 1934 and the "Operating regulations for cremation equipment" of 5 November 1935 as well as the "Decree concerning the application of the law on cremations" of 10 August 1938 were still in force in the Reich at that moment. On 13 March 1942, these laws were extended to the *Reichsgau* Sudetenland (Roland 1942, p. 62).

The official form concerning the transfer of the body to the head of the crematorium of a concentration camp also refers to the "Law on cremations" of 15 May 1934. In line with the rules regarding civilian cremations, the regulations concerning the transfer stipulate that "the cremation of the corpse must be carried out within 24 hours." At Stutthof Camp, this practice has been confirmed up to December of 1944 (cf. Document 292). This type of form was also in use at Auschwitz.[635]

The head of the crematorium had to keep a register in which were recorded the number of the funeral service, the last and first name of the deceased, the file number, the type of the detainee, his date of birth, his origin (town and county), the date of death, the number of the death certificate of the public registrar's office in charge of the place where the death had occurred – at the detainee hospital or elsewhere – the cause of death, the cremation date, the cemetery to which the urn was sent for burial, and any possible criminal record of the deceased:[636]

> *"The corpse will be cremated in the state crematorium. There are no objections to a shipment of the urn provided that a certificate of the administration of the local cemetery is issued to the effect that a regular interment will be carried out. Such a certificate is to be sent as soon as possible to the crematorium of Stutthof Concentration Camp near Danzig. The urn will be shipped free of charge. The death certificate is attached. You may request an official death certificate from the registrar's office of Stutthof Concentration Camp near Danzig. The personal belongings will be shipped presently.*
> *The camp commandant"*

634 NO-1510.
635 Reproduced in Blumental 1946, Vol. I, pp. 106f.; cf. Document 293.
636 AMS, I-VD-1; cf. Document 295.

Shipment of urns is also documented for the Mauthausen Camp, at least until March of 1942 (Document 296). At the Buchenwald Museum, a number of urns of various shapes are still preserved in a display case (Photos 364f.). Urns of a simpler type are also kept in a pavilion of the Mauthausen Museum (Photo 363).

The use of urns for the ashes of incinerated detainees was still mandatory in 1941. On 24 June, the head of the administration of the Gross-Rosen Camp sent to the Inspectorate of the Concentration Camps, which had its seat at Oranienburg north of Berlin, a request for "1,000 pcs. ash urns" to "preserve in an orderly fashion the corpse ash resulting" from the cremations.[637]

In the reply, dated 27 June, the Inspectorate of Concentration Camps advised that the purchase of ash urns was centralized with the company "Grosskopf, Ludwig & Co. of Ilmenau in Thuringia," to which the Gross-Rosen administration was to address their request for urns (as per DIN Standard 3198).[638] The letter asking for shipment of "1000 pcs. ash urns" was sent by this office on 11 July 1941.[639]

Initially, the Sachsenhausen legal requirements were applied also at Auschwitz. One of the first letters Topf sent to the New Construction Office opened with the following words (Document 297):

> *"For the start-up of the crematorium, you furthermore require ash urns, an imprinting device for the urn lids, and fireclay markers."*

For the immediate needs of the crematorium, Topf offered the supply of 500 ash urns DIN standard, of black sheet metal with a sheet-metal lid of the same color for the price of RM 675; 500 fireclay markers numbered 1 to 500, priced RM 65, and an imprinting device at 150 Reichsmarks.[640]

The numbered fireclay markers identified the ashes of the incinerated corpse. This manner of operation indicates a procedure in accordance with the applicable legal norms. The creation of a room for the urns (*Urnenraum*) within Crematorium I is already mentioned in the New Construction Office letter of 21 January 1941;[641] it was implemented by partitioning off a section of the morgue.[642]

On 29 April, the Political Department of the camp, which had authority over the crematorium, sent the following request to the New Construction Office (Document 298):[643]

> *"In line with the requirements of the Inspector of Concentration Camps, approved by* RSHA*, the ashes of the deceased detainees must be held in one of the*

In order for the urns to be collected in that room in an orderly fashion, appropriate shelves must be provided together with some other minor modifications. A specialist is requested for the inspection of the room and for the necessary preparations."*

Jean-Claude Pressac shows the photo of an urn from the Auschwitz Crematorium which contains the ashes of Karl Witalski, who died on 28 March 1941 and was cremated on 2 April (Pressac 1989, p. 133). These data are imprinted on the lid of the urn, which is of the same type as those shown in Photo 7 of Document PS 2430, which depicts an urn repository at the crematorium at Natzweiler Camp (*IMT*, Vol. 30, p. 429; see Photo 365). For Auschwitz, the use of urns is documented until November of 1941. From the few documents to have survived, we can gather that, since 6 January 1941, the Political Department of the camp requested from the carpentry workshop of the New Construction Office the fabrication of hundreds of "cases" and "boxes" for urns.[644] The latest known request, dated 27 November 1941, refers to 50 "urn-shipment boxes"[645] (Documents 299f.).

The cases or boxes for the urns were used as packing cases for the shipment of urns to the cemetery of the place of residence of the relatives or to some other cemetery, in keeping with Section 4, Paragraph 7 of Himmler's decree of 28 February 1940, after telegraphic notification by the camp commandant of the death of the detainees, as per Section 3, Sub-Section 1 of this decree.[646]

In some cases, shipment of urns was prohibited by the SS authorities for reasons of public order.

On 28 May 1941, the *Befehlshaber der Sicherheitspolizei und des SD* in the Government General informed the camp commandant at Auschwitz that he had submitted to the *RSHA*, on 21 April, a proposal concerning the "shipment of ash urns of deceased persons." The proposal contained, *i.a.*, the following procedure:[647]

> *"Shipment of urns to the Government General will no longer be effected; instead, the relatives will be informed immediately that an interment of the urns has taken place at the urn cemetery."*

This measure was intended to prevent the urns from being turned into objects of anti-German propaganda, as the head of Office Group D of the *WVHA* makes clear in a circular to the commandants of all concentration camps dated 12 September 1942. In this letter, which concerns the "Shipment of urns of detainees who died in the concentration camps," *SS Obersturmbannführer* Liebehenschel noted that urns with the ashes of Czechs or Jews sent back to the Protectorate of

646 Cf. telegram of 19 January 1942 announcing the death of detainee Aleksander Glodek, deceased two days earlier, in: Staatliches Museum Auschwitz 1995, Vol. 1, p. 132 of Appendix of documents.

647 AGK, NTN, 94, p. 166.

Bohemia and Moravia had provoked demonstrations, processions, etc. For that reason, he prohibited, with immediate effect, the shipment of such urns to the Protectorate, adding:[648]

> *"The urns will be preserved in the concentration camps. In case of doubt concerning the preservation of the urns, oral instructions are to be requested from this office."*

Aside from the system of completely direct incineration which, in actual operation, was also frequently practiced in civilian crematoria, we can say that the Topf Furnaces for concentration camps were designed and built in accordance with the ethical and legal norms applicable at the time. In fact, in the cost estimates for the double- and triple-muffle furnaces, carts or devices for the introduction of coffins into the muffle were specifically mentioned, which means that cremation with a coffin was provided for.[649]

This is confirmed by the operating instructions of these furnaces (Documents 210 and 227), which specified the start-up of the blower immediately after the introduction of the corpse into the muffle and maintaining it for some 20 minutes. This practice is completely consistent with corpses introduced into the muffle in coffins, because the rapid and intensive combustion of the coffin required large amounts of air,[650] whereas it is wasteful for a cremation without a coffin, because feeding large amounts of cold air into the muffle during the vaporization phase of the corpse water – a period during which a considerable amount of heat was drained from the furnace – would only have impeded the cremation process.

The coffins used were probably similar to those used in the Terezín Crematorium (cf. Photo 362).

We may also deduce from Topf's operating instructions that the double- and triple-muffle furnaces were designed to cremate a single corpse at a time and to ensure, if the instructions were correctly applied, segregation of the ashes of the corpses cremated.

We must, therefore, accept as a fact that, with regard to the design of their furnaces, the Topf Company and Engineer Prüfer in particular took into account the usual requirements of decorum and respect.

---

[648] NO-1510.

[649] Even the metal stretcher of simplified design which succeeded these devices was called *Sargeinführtrage*, stretcher for coffin introduction.

[650] For this reason, the first electric furnace built by Topf at Erfurt was equipped with a blower having a capacity of 1,000 m³/hr for a pressure of 200 mm of water column; Jakobskötter 1941, p. 580.

1.3. Summary of the Topf Company's Activities at Auschwitz-Birkenau

The Topf Company's area of activities was not strictly limited to cremation furnaces, as outlined in Unit II of this study. It extended into two other important areas: ventilation systems and disinfestations with hot air. The table below lists almost all deliveries ever made, and projects carried out, by Topf at the Auschwitz-Birkenau Camp. These activities yielded a turnover of more than 240,000 Reichsmarks to this Erfurt firm. Where data are unknown, the respective cell is left blank. Date format is dd/mm/yyyy.

Invoice Date	Order No.	Amount RM	Date of Cost Estimate	Object	Building*
27/08/1940		10,679	17/4/1940	Furnace No. 1	K I
	40 D 945	146	9/10/1940 (A)	11 muffle-grate bars, 200 kg of compressed Monolite	K I
	40 D 1090	7,753	13/11/1940	Furnace No. 2	K I
?/01/1941	41 D 38	300			K I
15/01/1941	41 D 73	444		sending a technician	K I

1.4. Patents (and Patent Applications) by J.A. Topf & Söhne

Patents on cremation furnaces are in italics.[651]

Ref. No.	Country	Pat. No.	Object
/	Germany	324252	*Sargeeinführvorrichtung für Verbrennungsöfen mit heb- und senkbarem Fahrgestell für den Sargträger*
/	Germany	493042	*Vorrichtung zum Nachverbrennen der Rückstände in Leichenverbrennungsöfen*
28/2	Germany	494136	Ausfahrbarer Schlackenrost für mit Unterwind betriebe-ne Feuerungen
34/2	Germany	561643	*Feuerbestattungsofen mit drehbaren Rosten*
31/12	Germany	576135	Düsenplattenrost
32/9	Germany	587149	Verfahren u. Ofen zur Zurückgewinnung von Blei und Kupferdraht aus Kabeln
37/2	Germany	592658	Saugdüse
35/1	Germany	608462	Wendeschraube f. mech. Wendeapparate
29/5	Germany	612193	Verfahren z. gliechzeitigen Weichen und Ankeimen von Malz
32/3	Germany	621449	Luft- Zu- u. -Abführungs-Vorrichtung an drehbaren Tro-ckentrommel m. Geschlossenem Aussenmantel
34/1	Germany	633197	Kegelförmige Absperrvorrichtung
38/1	Germany	638582	*Einäscherungsofen*
35/2	Germany	651506	Belüftungs-Einrichtung für staubförmige oder staubhal-tige Massengüter

[651] Thüringische Verwaltungsstelle – Kreisstelle Erfurt, Erfurt, Hindenburgstrasse. Patente der Firma J.A. Topf & Söhne, Erfurt, 20 November 1945. SE, 5/411 A 172. The list was completed with the results of our research.

Ref. No.	Country	Pat. No.	Object
36/2	Germany	659405	*Beschickungseinrichtung für Einäscherungsöfen*
38/4	Germany	695325	Mehrhorden-Malzdarre
38/4	Germany	718946	Mehrhorden-Malzdarre
41/11	Germany	721513	Gutbehälterauslauf für Saugförderanlagen in Speichern mit Mehreren Gutbehältern
41/7	Germany	724940	Verfahren und Vorrichtung zur selbsttätigen Belüftung von Getreideweichen mit mehreren Weichge- fässen
41/4	Germany	724941	Vorrichtung zur selbsttätigen Regelung der Arbeitsvorgänge von Kasten-Keimtrommeln
41/8	Germany	728405	Kuppelvorrichtung für Kasten-Keimtrommeln
41/6	Germany	728529	Vorrichtung zum selbständigen Regeln des Bewegungsvorganges von Malzwendern, insbesondere von Keimkästen
41/12	Germany	733328	Vorrichtung zum Pressen und Imprägnieren von Malzkeimen oder anderen landwirtschaftlichen Abfallstoffen
/	Germany	patent appl.	*Kontinuierlich arbeitender Leichen-Verbrennungsofen für Massenbetrieb*
/	Germany	patent appl.	Luftgekühlte Rostplatten für Vorschubroste
42/5	Germany	756205	Rückmelde- oder Sicherheitsschalter
/	Germany	861731	*Verfahren und Vorrichtung zur Verbrennung von Leichen, Kadavern und Teilen davon*
25/6	USA	1596977	Kastentrommel
30/17	France	710023	Keimkasten mit fahrbarem Wender
25/8	Switzerland	65465	Kastentrommel
41/18	Switzerland	216678	Mehrhorden-Malzdarre

1.5. Patent Applications by Department "DE" of J.A. Topf & Söhne

Date format: dd/mm/yyyy.[652]

Ref. No.	Protocol No.	Object	Request Date
D 39/1	T 52 739 V/24 f	Mechanischer Stufenrost m. Wasserlaufkühlung	25/08/1939
D 39/2	T 52 961 V/24 f	Rostbelag zu mechanischen Stufenrosten	21/10/1939
D 39/3	T 53 166 V/24 d	*Einäscherungsofen mit Doppelmuffel*	06/12/1939
D 41/4	T 56 022 V/24 f	Mechanischer Vorschubrost mit gekrümmten Rostplattenträgern	05/08/1941
D 41/5	T 56 340/V 24 f	Mechanischer Zonen-Vorschub-Rost	15/10/1941
D 42/3	T 58 240/V 24 d	*Kontinuierlich arbeitender Leichen-Verbrennungsofen für Massenbetrieb*	05/11/1942
D 42/4	T 58 282/V24 f	Luftgekühlte Rostplatten für mechanische Vorschubroste	16/11/1942
D 42/6	T 58 411 /V82 a	Querstromtrockner für körnige Brennstoffe u. andere Schüttgüter mit vor- u. nachgeschalteten-Mahlgang	17/12/1942
D 42/7	T 58 449 III/30 c	Mühle für Brennstoffe u. andere Schüttgüter	17/12/1942
D 43/1	T 58 825 V/24 i	Schornstein und Entlüftungsaufsatz	10/03/1943

D 44/1	/	Verfahren zur mechanischen Längs- und Querschürung des Brennstoffbettes bei mechanischen Schürrosten	10/03/1944

- Description of patents sent to the patent office of the German Reich:
  - *Hochleistungsofen mit Aschendrehrost D.R.P. angem.*, 1934.
  - *Elektrisch betriebener Topf-Einäscherungsofen D.R.P. angem.*, 1935.

2. Glossary

Abfall-Vernichtungs-Ofen	Waste-disposal incinerator
Abgase	exhaust/smoke/flue gas
Abgaskanäle	exhaust/flue-gas channels
Abgasventilator	exhaust fan
Absperrschieber	closing slide/damper
Absperrventil	closing valve
Achtmuffel-Einäscherungsofen	eight-muffle cremation furnace
Anker	anchor irons/rods, drawing rods
Armaturen	fittings, displays
Asche-Urne, Ascheurne	ash urn
Ascheabkühlkammer	ash-cooling chamber
Ascheausbrennkammer	ash post-combustion chamber
Aschebehälter	ash container
Aschedrehrost	tiltable ash grate
Ascheentnahmerost	ash-removal grate
Ascheentnahmetür	ash-removal door
Aschekapsel	ash capsule, urn
Aschekasten	ash container
Aschenaufnahmebehälter	ash container
Aschenraum	ash chamber
Aschenschräge	ash slope
Aschentransportvorrichtung	ash-transport device
Auflager-Eisen	supporting iron bars (transverse)
Ausbrennraum	chamber to complete combustion
Ausglührost	post-combustion grate
äusseres Ziegelmauerwerk	external brick masonry
Befestigungs-Eisen	holding iron bar
Beharrungszustand	steady state
Beheizung	heating
Beladung	loading
Belastung	load, strain
Beschickungseinrichtung	loading device
Beschriftungs-Apparat	labeling device
Betriebsvorschrift	operating instruction
Brenner	burner
Brennereinstellung	burner adjustment
Brennkammer	cremation chamber
Brennstoff	fuel
Brennstofflager	fuel storage
Brennstoffverbrauch	fuel consumption
Brikett	briquette
D.R.P. (Deutsches Reichspatentamt)	patent office of the German Reich
Dauerbetrieb	continuous operation
DIN (Deutsche Industrie-Norm; Deutsches Institut für Normung)	German industrial standard; since 1975: German Institute for Standardization
direkte Einäscherung	direct cremation
Doppelmuffel Einäscherungsofen	double-muffle cremation furnace
Drahtseil	wire cable

drehbare Asche-Sammelplatte	tiltable ash-collection grate
Drehklappe	rotary vane
Drehrost	tiltable grate
Drehrostplatte	tiltable grate panel
Drehscheibe	rotatable platform
Dreimuffel-Einäscherungsofen	triple-muffle cremation furnace
Druckluftleitung	compressed-air conduits
Dunsthaube	fume (extractor) hood
Einäscherung	cremation
Einäscherungsanlage	cremation facility
Einäscherungskammer	cremation chamber
Einäscherungsofen	cremation furnace
Einäscherungsraum	cremation room/hall
Einäscherungsverfahren	cremation method
Einführrollen	introduction rollers
Einführtrage	introduction stretcher
Einführtür	introduction door
Einführungsschieber	introduction
Einführungstür	introduction door
Einführungswanne	introduction tub
Einmuffel-Einäscherungsofen	single-muffle cremation furnace
Entaschung	ash removal
Entwesungsofen	disinfestation furnace
Essengas	flue gas
Essenkanal	flue channel
Etageofen	multi-story furnace
Exhaustor	exhauster, extraction fan
fahrbarer Ofen	mobile furnace
Fahrgestell	chassis
Falschluft	unwanted air
Feldofen	field furnace
feuerbeständig	fire-resistant
Feuerbestattung	cremation
Feuerbestattungsofen	cremation furnace
Feuerbestattungsanlage	cremation facility
Feuerbrücke	fire bridge
feuerfest	fire-proof
Feuertür	fire door/hearth door
Feuerung	firing/firebox
Flachbettofen	flatbed furnace
Flugaschefreie-Verbrennungsgase	combustion gases free of fly ash
Flugasche	fly ash
Flugaschen-Entstaubungsanlage	fly-ash-removal device
Formstein	cinder block
Frischluftventilator	fresh-air fan
Fuchs	flue
Fuchseinsteigeschachtverschluss	lid of flue access shaft
Führungsrollen	guide rollers
Füllschachtverschluss	closure of loading shaft
Gasabzug	gas/smoke/exhaust duct
gasbeheizt	gas-fired
Gaserzeuger	gas generator/gasifier
Gasfeuerung	gas-fired system
Gaskanal	gas channel

Gaskoks	gas coke
Gebläse	fan, blower
Gegengewicht	counter weight
Generator	generator/gasifier
Generatorfüllschacht	generator-/gasifier-loading shaft
Generatorfüllschachtverschluss	closure of generator-/gasifier-loading shaft
Generatorfülltür	door of generator-/gasifier-loading shaft
Generatorgase	generator gas, producer gas
Generatorhals	generator/gasifier neck
Generatorschacht	generator/gasifier shaft
geruchlos	odorless
Gewölbe	vault
Gleis zur Beschickung der Öfen	rails for loading the furnaces
Gleis zur Kokszufuhr	rails for coke delivery
Gleittür	sliding door
halbindirekte Einäscherung	semi-indirect cremation
Halbwölber	semi-wedge bricks
Handwinde	hand crank
Hauptbrenner	main burner
Hauptbrennraum	main combustion chamber
Hauptfeuerung	main hearth
Hauptkanalschieber	main-channel/duct/flue damper
Hauptverbrennung	main combustion
Heisslufteinäscherungsofen	hot air cremation furnace
Heizfläche	heating surface
Heizgase	heating gases
Heizkammer	heating chamber, of recuperator
Heizschlange	heating coil
Heizspirale	heating coil, heating element
Heizspule	heating coil
Heizung	heating
Heizversuch	heating experiment
Hochheizung	heating/firing up
Holzfeuerung	wood-fired system
Hüttenkoks	foundry coke
indirekte Einäscherung	indirect cremation
Isolierabsperrschieber	insulating damper
Isoliermörtel	insulation mortar
Isolierstein	insulation brick
Isolierung	insulation
Kamineinband	chimney framing
Kaminfeuer	chimney fire
Keilstein	wedge brick
Kieselgurmörtel	diatomaceous-earth mortar
Kieselgurstein	diatomaceous-earth stone
Klemme	clamp
Kohlenbeschickungsvorrichtung	coal-loading device
Kohlensäuregehalt	CO_2 content
Kohlentransportwagen	coal transportation cart
Koks	coke
koksbeheizt	coke-fired
Koksfeuerung	coke-fired system
Koksofen	coke furnace
Kratze	scraper

Kremation	cremation
Kremationsofen	cremation furnace
Krematorium	crematorium
Laufrolle	guide roller/wheel
Laufschiene	guide rail
Leicheneinäscherungsofen	corpse-cremation furnace
Leicheneinführungs-Vorrichtung	corpse-introduction device
Leichenhalle	corpse hall, morgue, mortuary
Leichenkeller	corpse basement, underground morgue
Leichenraum	corpse room, morgue
Leichentrage	corpse stretcher
Leichenverbrennung	corpse cremation
Leichenverbrennungsofen	corpse-cremation furnace
Leistung	power, performance
Lockfeuer	pilot flame
Luftabschlussklappe	air shutter
Luftabschlussschieber	airclosing slider/damper
Luftaustrittdüsen	air-exhaust nozzle
Luftdüsen	air nozzle
Lufteintritt	air-feed opening
Lufterhitzer	air heater
Lufterhitzrohr	air-heating pipe
Luftgas	air gas
Luftkammer	air chamber
Luftkanal	air channel
Luftkanalverschluss	closure for air channel
Luftklappe	air shutter
Luftrosette	air rosette
Luftschieber	air damper
Luftüberschuss	air excess
Luftverteiler	air manifold
Luftzuführung	air supply
Luftzutritt	air intake
Mauerwerksmantel	outer brickwork
mm WS (Wassersäule)	mm water column (pressure)
Monolit	Monolite
Motor-Raum	engine room
Muffel	muffle
Muffelabsperrschieber	sliding muffle closure
Muffelgewölbe	muffle vault
Müllverbrennungsofen	waste incinerator
Müllverbrennungsraum	waste incinerator room
Nachbrennkammer	post-combustion chamber
Nachbrennraum	post-combustion chamber
Nachglühraum	post-combustion chamber
Nachverbrennungskanäle	post-combustion channels
Nachverbrennung	post-combustion
Nachverbrennungsrost	post-combustion grate
Nebenbrenner	auxiliary burner
Normalstein	standard brick
Normalverbrennung	standard combustion
Notkrematorium	makeshift crematorium
Oberluft	upper air supply
Ofenanlage	furnace facility

Ofengruppe	furnace group
Ofenmantel	furnace
Ofenschieber	furnace damper
offene Verbrennungskammer	open combustion chamber
offene Verbrennungsstätte	open cremation site
ölbeheizt	oil-/naphtha-fired
Ölbrenner	oil/naphtha burner
Ölfeuerung	oil/naphtha firing
Ölvorwärmer	oil/naphtha pre-heating
Patentanmeldung	patent application
Patentanspruch	patent claim
Patenterteilung	patent issuance
Patentschrift	patent specification
Pfanne	pan
Planrost	flat grate
Planroststäbe	flat-grate bars
primäre Luft	primary air supply
Probeeinäscherung	cremation experiment
Prunktür	decorative door
Rauchabzug	smoke duct
Rauchgasabzug	smoke-gas duct
Rauchgasausnutzung	exploitation of smoke gas (heat)
Rauchgase	smoke/exhaust/discharge gases
Rauchgasnachbrennkammer	smoke-gas post-combustion chamber
Rauchgasventilator	smoke-gas fan
Rauchkanal	smoke duct/flue
Rauchkanalschieber	smoke-duct damper
Rauchkanalschieberrahmen	frame of flue damper
rauchlos	smokeless
Rauchverbrennung	smoke combustion
Reform-Einäscherungsofen	improved cremation furnace
Regenerator	regenerator
Regulierhebel	control lever
Regulierventil	control valve
Reichspatentamt	Reich Patent Office
Reinigungstür	cleaning door
Rekuperation	recuperation
Rekuperator	recuperator
Reserveofen	back-up furnace
Ring-Einäscherungsofen	ring cremation furnace
Ring-Ofen	ring furnace
Rohrgabel	tube yoke
Rohrleitung	piping
Rollenbock	roller stand/stretcher support
Rost-Auflager	grate support
Rostauflagerbalken	beam for grate support
Rückstände	remnants, remains
Rundeisenanker	round iron anchors
Sarg	coffin
Sargbrückenstein	coffin-support stone
Sargeinführtrage	coffin-introduction stretcher
Sargeinführungsvorrichtung	coffin-introduction device
Sargeeinführungswagen	coffin-introduction cart
Saugzug-Anlage	forced-draft device

Saugzug-Gebläse	forced-draft blower
Schacht	shaft
Schamotte	refractory clay, fireclay
Schamotteabsperrplatte	refractory damper
Schamotteausmauerung	refractory lining
Schamottefutter	refractory lining
schamottegefüttert	lined with refractory clay
Schamottemarken	refractory tags
Schamottemauerwerk	refractory masonry
Schamottemörtel	refractory mortar
Schamotterost	refractory grate
Schamotteroststeine	refractory grate bars
Schau-Öffnung	inspection opening
Schauloch	inspection hole
Schauluke	inspection port
Schieberplatte	damper plate
Schlacke	slag, cinder
Schlackenwolle	slag wool
Schlangensystem	coil system
Schornstein	chimney, smokestack
Schornsteinmantel	outer chimney masonry
Schornsteinrohr	chimney pipe
Schrägrost	slanted/sloping grate
Schrägroststäbe	slanted/sloping grate bars
Schürgeräte	poker
Schürstange	poking bar
Schwadenabsaugung	fume extraction
Seilkausche	rope thimble
Seilrolle	cable pulley
Seitenluft	lateral air (supply)
sekundäre Luft	secondary air
SK (Segerkegel)	Seger cone
Sohle	bottom, floor
Spannschraube	clamping/tension screw
Spiralenrekuperator	coil recuperator
Stampfmasse	caulking/packing mass/mix
Steigeisen	climbing/step iron
Stundenleistung	hourly performance
T-Eisen	T-iron
termisches Gleichgewicht	thermal equilibrium
Tierleichen-Verbrennungsöfen	animal-carcass-incineration furnace
Trage	stretcher
Trockenheizung	heat drying
Trocknung	drying out, desiccation
Türplatte	(refractory) door plate
U-Eisen	U-iron
Umführungsrauchkanal	flue/smoke duct
Umleitung der Kohlenoxydgase	diversion of CO gases
Urne	urn
Urnenkasten	urn case
Urnenkisten	urn box
Urnenraum	urn room
Ventilator	ventilator, fan
Verankerung	anchoring, bracing

Verankerungs-Eisen	anchoring/bracing (iron) bar
Verbrennung	combustion
Verbrennungsgase	combustion gases
Verbrennungsgegenstand	combustion object
Verbrennungsraum	combustion chamber
Versandkasten	shipping box
Verschiebwagen	relocation cart
Vierkanteisen	square iron
Vierkantstäbe	rectangular bars
Vorheizung	preheating
Vorwärmer	preheater
Wärmebelastung	thermal load/stress
Wärmebilanz	heat/thermal balance
Wärmespeicher	heat accumulator/reservoir
Wasserbehälter	water container
Wassergas	water gas
Windleitung	blast pipe
Winkeleisen	angle iron
Wirkungsgrad	efficiency (rate/factor)
Wölbstein	arch brick
Zentner	50 kg
Zug	chimney duct or draft
Zugmesser	draft gauge
Zugstärke	draft strength/intensity
Zugverstärkungs-Anlage	Draft-improvement device

3. Symbols

Not included are chemical (element) symbols.

α = Heat-transfer coefficient (*Wärmeübergangszahl*) = $^1/_{273}$ °C^{-1}
γ = specific density
η = efficiency factor (*Wirkungsgrad*)
λ = thermal conductivity (*Wärmeleitzahl*; in kcal m^{-1} °C^{-1} h^{-1})
σ = radiation ratio (*Ausstrahlungsverhältnis*)
A = ashes (*Aschen*)
B = fuel (*Brennstoff*)
BTU = British Thermal Unit (1 BTU = 0.252 Kcal)
c_p = specific heat (*spezifische Wärme*)
c_{pm} = average specific heat (*mittlere spezifische Wärme*)
F = surface, area (*Fläche*)
G = weight (*Gewicht*)
H_o = u.h.v., upper heating value (*oberer Heizwert*)
hp = horsepower
H_u = l.h.v., lower heating value (*unterer Heizwert*)
H_{ua} = lower heating value of ashes (*Unterer Heizwert Asche*)
i = heat, enthalpy (thermal contents)
K = thermal transmittance (*Wärmedurchgangszahl*)
L = air (*Luft*)
m = Excess-air ratio (*Luftverhältnis*)
q = cross-sectional area of chimney (*Querschnitt*)
PS = horsepower (*Pferdestärke*)
R = smoke gas (*Rauchgase*)
R_g = weight of smoke gas (*Rauchgase Gewicht*)
R_v = heat loss via smoke gas (*Rauchgase Verlust*)
U = uncombusted (*Unverbranntes*)
V = heat loss (*Verlust*)
V_a = heat loss via ashes and slag (*Verlust Asche*)
V_{ls} = heat loss via masonry by conduction and radiation (*Verlust Leitung-Strahlung*)
V_{sch} = heat loss via chimney (*Verlust Schornstein*)
V_{un} = heat loss via uncombusted gas (*Verlust unverbrannt*)
W = heat (*Wärme*) / water (*Wasser*)
WS = water column (*Wassersäule*): 1 mm WS = 1 kg/m^2
Z = time (*Zeit*)

4. Abbreviations of Archive Names

AGK	Archiwum Głównej Komisji Badania Zbrodni Przeciwko Narodowi Polskiemu Instytutu Pamieci Narodowej (Archive of the Central Commission for the Investigation of Crimes against the Polish People, National Memorial) now *Instytut Pamięci Narodowej* (Institute for national Commemoration), Warsaw
AKfSD	Archiv des Kuratoriums für Sühnemal KZ Dachau (Archive of the Foundation for Atonement at KZ Dachau)
AMS	Archiwum Muzeum Stutthof (Archive of the Museum at Stutthof)
APMGR	Archiwum Panstwowego Muzeum Gross-Rosen (Archive of National Museum of Gross-Rosen), Wałbzrych
APMM	Archiwum Panstwowego Muzeum na Majdanku (Archive of National Museum at Majdanek)
APMO	Archiwum Panstwowego Muzeum w Oswiecimiu (Archive of National Museum at Auschwitz)
BAK	Bundesarchiv Koblenz
DPA	Deutsches Patentamt, Berlin
FSBRF	Federal'naja Služba Bezopasnosti Rossiskoi Federatsii, (Federal Security Office of the Russian Federation), Moscow
GARF	Gosudarstvenni Archiv Rossiskoi Federatsii (National Archive of the Russian Federation), Moscow
IMT	Trial of the Major War Criminals before the International Military Tribunal, published in Nuremberg 1947
KfSD	Kuratorium für Sühnemal KZ Dachau
ÖDMM	Öffentliches Denkmal und Museum Mauthausen
PRO	Public Record Office, London
PT	Památník Terezín (Terezín/Theresienstadt Monument)
ROD	Rijksinstituut voor Oorlogsdocumentatie (National Institute for War Documentation), Amsterdam
SB	Sennefriedhof Bielefeld
SE	Stadtarchiv Erfurt
SW	Staatsarchiv Weimar
RGVA	Rossiysky gosudarstvenny voyenny arkhiv (Russian State War Archive), Moscow
VHA	Vojensky Historicky Archiv (Archive of Military History), Prague
WAPL	Wojewódzkie Archiwum Panstwowe w Lublinie (National Provincial Archive, Lublin)

Deutsches Reich. Reichspatentamt. Patentschrift No. 324252. Klasse 24d. Gruppe 1. Ausgegeben am 24. August 1920. J.A. Topf & Söhne in Erfurt. *Sargeinführvorrichtung für Verbrennungsöfen mit heb- und senkbarem Fahrgestell für Sargträger*. Patentiert im Deutschen Reiche vom 24. April 1915 ab.

Deutsches Reich. Reichpatentamt. Patentschrift No. 331628. Klasse 24d. Gruppe 1. Ausgegeben am 11. Januar 1921. Adolf Marsch in Gera, Reuss. *Schachtofen zur gleichzeitigen Einäscherung einer grösser Anzahl von Menschenleichen oder Tierkadavern*. Patentiert im Deutschen Reiche vom 30. September 1915 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 493042. Klasse 24d. Gruppe 1. Ausgegeben am 5. März 1930a. J.A. Topf & Söhne in Erfurt. *Vorrichtung zum Nachverbrennen der Rückstände in Leichenverbrennungsöfen*. Patentiert im Deutschen Reiche vom 24. März 1929 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 494136. Klasse 24f. Gruppe 10. Ausgegeben am 19. März 1930b. J.A. Topf & Söhne in Erfurt. *Ausfahrbarer Schlackenrost für mit Unterwind betriebene Feuerungen*. Patentiert im Deutschen Reiche vom 22. August 1928 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 506627. Klasse 24d. Gruppe 1. Ausgegeben am 6. September 1930c. Tag der Bekanntmachung über Erteilung des Patents: 28. August 1930. Dipl.-Ing. Hans Volckmann und Dipl.-Ing. Karl Ludwig in Hamburg. *Verfahren und Vorrichtung zur Einäscherung*.

Deutsches Reich. Reichspatentamt. Patentschrift No. 561643. Klasse 24d. Gruppe 1. Ausgegeben am 17. Oktober 1932 (Viktor Quehl in Gera). Umgeschrieben auf: J.A. Topf & Söhne, Erfurt. 17.5.1934. *Feuerbestattungsofen mit drehbaren Rosten*. Patentiert im Deutschen Reiche vom 15. April 1931 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 576135. Klasse 24f. Gruppe 12 02 1560. Ausgegeben am 20. Mai 1933a. J.A. Topf & Söhne in Erfurt. *Düsenplattenrost*. Patentiert im Deutschen Reiche vom 27. August 1931 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 587149. Klasse 24f. Gruppe 1202. Ausgegeben am 31. Oktober 1933b. J.A. Topf & Söhne in Erfurt. *Verfahren und Ofen zur Zurückgewinnung von Blei und Kupferdraht aus Kabeln*. Patentiert im Deutschen Reiche vom 29. September 1932 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 638582. Klasse 24d. Gruppe 1. Ausgegeben am 19. November 1936. (Wilhelm Basse in Hamburg). Umgeschrieben auf: J.A. Topf & Söhne, Erfurt. 27.11.1937. *Einäscherungsofen*. Patentiert im Deutschen Reiche vom 20.Novembre 1936 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 659405. Klasse 24d. Gruppe 1. Ausgegeben am 4. Mai 1938a. Hans Geerhardt in Erfurt ist als Erfinder benannt worden. J.A. Topf & Söhne in Erfurt. *Beschickungseinrichtung für Einäscherungsöfen*. Patentiert im Deutschen Reiche vom 20. November 1936 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 669645. Klasse 24d. Gruppe 1. Ausgegeben am 31. Dezember 1938b. Firma Wilhelm Ruppmann in Stuttgart. Tag der Be-

kanntmachung über die Erteilung des Patents: 8. Dezember 1938. *Leichenverbrennungsofen*. Patentiert im Deutschen Reiche vom 23. Juni 1936 ab.

5.2.1.7.Patents

Bundesrepublik Deutschland. Deutsches Patentamt. Patentschrift No. 861731. Klasse 24d. Gruppe 1. Ausgegeben am 5. Januar 1953. Martin Klettner, Recklinghausen, ist als Erfinder genannt worden. J.A. Topf & Söhne, Wiesbaden. *Verfahren und Vorrichtung zur Verbrennung von Leichen, Kadavern und Teilen davon*. Patentiert im Gebiet der Bundesrepublik Deutschland vom 24. Juni 1950 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 324252. Klasse 24d. Gruppe 1. Ausgegeben am 24. August 1920. J.A. Topf & Söhne in Erfurt. *Sargeinführvorrichtung für*

Verbrennungsöfen mit heb- und senkbarem Fahrgestell für Sargträger. Patentiert im Deutschen Reiche vom 24. April 1915 ab.

Deutsches Reich. Reichpatentamt. Patentschrift No. 331628. Klasse 24d. Gruppe 1. Ausgegeben am 11. Januar 1921. Adolf Marsch in Gera, Reuss. *Schachtofen zur gleichzeitigen Einäscherung einer grösser Anzahl von Menschenleichen oder Tierkadavern*. Patentiert im Deutschen Reiche vom 30. September 1915 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 493042. Klasse 24d. Gruppe 1. Ausgegeben am 5. März 1930a. J.A. Topf & Söhne in Erfurt. *Vorrichtung zum Nachverbrennen der Rückstände in Leichenverbrennungsöfen*. Patentiert im Deutschen Reiche vom 24. März 1929 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 494136. Klasse 24f. Gruppe 10. Ausgegeben am 19. März 1930b. J.A. Topf & Söhne in Erfurt. *Ausfahrbarer Schlackenrost für mit Unterwind betriebene Feuerungen*. Patentiert im Deutschen Reiche vom 22. August 1928 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 561643. Klasse 24d. Gruppe 1. Ausgegeben am 17. Oktober 1932 (Viktor Quehl in Gera). Umgeschrieben auf: J.A. Topf & Söhne, Erfurt. 17.5.1934. *Feuerbestattungsofen mit drehbaren Rosten*. Patentiert im Deutschen Reiche vom 15. April 1931 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 576135. Klasse 24f. Gruppe 12 02 1560. Ausgegeben am 20. Mai 1933a. J.A. Topf & Söhne in Erfurt. *Düsenplattenrost*. Patentiert im Deutschen Reiche vom 27. August 1931 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 638582. Klasse 24d. Gruppe 1. Ausgegeben am 19. November 1936. (Wilhelm Basse in Hamburg). Umgeschrieben auf: J.A. Topf & Söhne, Erfurt. 27.11.1937. *Einäscherungsofen*. Patentiert im Deutschen Reiche vom 20.Novembre 1936 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 659405. Klasse 24d. Gruppe 1. Ausgegeben am 4. Mai 1938a. Hans Geerhardt in Erfurt ist als Erfinder benannt worden. J.A. Topf & Söhne in Erfurt. *Beschickungseinrichtung für Einäscherungsöfen*. Patentiert im Deutschen Reiche vom 20. November 1936 ab.

Deutsches Reich. Reichspatentamt. Patentschrift No. 669645. Klasse 24d. Gruppe 1. Ausgegeben am 31. Dezember 1938b. Firma Wilhelm Ruppmann in Stuttgart. Tag der Bekanntmachung über die Erteilung des Patents: 8. Dezember 1938. *Leichenverbrennungsofen*. Patentiert im Deutschen Reiche vom 23. Juni 1936 ab.

Kaiserliches Patentamt. Patentschrift No. 218581. Klasse 24d. Ausgegeben den 8. Februar 1910. Max J. Kergel in Beuthen, O.-S. *Leichenverbrennungsofen mit Rekuperator*. Patentiert im Deutschen Reiche vom 4. Oktober 1908 ab.

Kaiserliches Patentamt. Patentschrift No. 244887. Klasse 24d. Ausgegeben den 20. März 1912. Lawson Henry Giddings in Pasadena, Calif. *Elektrischer Leichenverbrennungsofen*. Patentiert im Deutschen Reiche vom 11. April 1911 ab.

Kaiserliches Patentamt. Patentschrift No. 257576. Klasse 24d. Ausgegeben den 13. März 1913a. Gebr. Körting Aktiengesellschaft in Linden b. Hannover. *Leichenverbrennungsofen mit Ölfeuerung*. Patentiert im Deutschen Reiche vom 30. Juni 1911 ab.

Kaiserliches Patentamt. Patentschrift No. 258066. Klasse 24d. Ausgegeben den 28. März 1913b. Friedrich Siemens in Berlin. *Leicheneinäscherungsofen mit Regeneratoren und einem Gaserzeuger*. Patentiert im Deutschen Reiche vom 18. August 1911 ab.

Kaiserliches Patentamt. Patentschrift No. 263725. Klasse 24d. Ausgegeben den 6. September 1913c. Bunzlauer Werke Lengerdorff & Comp. in Bunzlau i. Schles. *Verfahren und Vorrichtung zur Einäscherung von Leichen mit Verbrennungsgasen und Lufterhitzer mit einer Wärmequelle*. Patentiert im Deutschen Reiche vom 6. Juli 1911 ab.

Kaiserliches Patentamt. Patentschrift No. 279830. Klasse 24d. Ausgegeben den 29. Oktober 1914. Wilhelm Buess in Hannover. *Leichenverbrennungsofen mit Öl- oder Gasfeuerung mit einem unter dem schräg abfallenden Verbrennungsraum liegenden Aschenaufnahmebehälter*. Patentiert im Deutschen Reiche vom 22. August 1913 ab.

Kaiserliches Patentamt. Patentschrift No. 284163. Klasse 24d. Ausgegeben den 12. März 1915. Wilhelm Sauerland in Dresden. *Einäscherungsofen mit an der einen Stirnseite mit dem Verbrennungsraum verbundenem Gaserzeuger und einem Regenerator.* Patentiert im Deutschen Reiche vom 19. Dezember 1912 ab.

Topf, J.A., & Söhne, Erfurt. Patentanmeldung. 26.10.1942a. "Kontinuierlich arbeitender Leichen-Verbrennungsofen für Massenbetrieb."

Topf, J.A., & Söhne, Erfurt. Patentanmeldung. 16.11.1942b. "Luftgekühlte Rostplatten für mechanische Vorschubroste."

5.2.1.8.Mass Cremations (Epidemics and Battlefields)

6. Indices

6.1. Names

This index contains only names of individuals of importance in the context of the present study which appear in the main text. In SMALL CAPS: designers, manufacturers and patent holders of crematoria and cremation systems; in *italics*: executives and employees of the company J.A. Topf & Söhne, Erfurt. Page numbers of entries in footnotes are set in italics.

Set in Times New Roman

Cover Illustrations: left: file memo by Engineer Kurt Prüfer of the Topf Company regarding the capacity of the Auschwitz cremation furnaces (Document 249); center: promotional brochure by the Topf Company for its electric and gas-fired cremation furnace (Document 140); right: blueprint (cross section) for a new crematorium at the Auschwitz camp (the later Crematorium II at Birkenau; Document 224).

Contents

Part 1: History and Technology (separate book)

Preface to the First Edition
Preface to the Second Edition

Unit I: Modern Cremation

1. The Cremation
   1.1. General Principles of Combustion Technology
   1.2. The Chemical Processes during Cremations
   1.3. The Cremation Process
2. Cremation Technology of Coke-Fired Furnaces
   2.1. Structure and Operation
   2.2. General Theoretical and Structural Principles
3. Origin and Development of Modern Cremation Furnaces
4. Cremation Experiments in Germany in the 1920s
5. Technical Developments of Cremation Furnaces in Germany in the 1930s
   5.1. Furnaces with Coke-Fed Gasifiers
   5.2. Furnaces Heated with City Gas
   5.3. Electrically Heated Furnaces
6. The Duration of the Cremation Process
   6.1. Cremation Furnace with a Coke-Fed Gasifier
   6.2. Cremation Furnace with Briquette-Fed Gasifier
   6.3. Cremation Furnace Heated with Gas
   6.4. Cremation Furnace Fired Electrically
7. Heat Balance of a Coke-Fed Cremation Furnace
8. Legal, Ethical and Professional Standards for Cremations in Germany
9. Cremation Statistics
   9.1. Statistics for Germany (1878-1939)
   9.2. Statistics of Other Countries
10. Mass Cremation for Hygienic and Sanitary Purposes
11. Notes on Present-Day Cremation Furnaces

Unit II: J.A. Topf & Söhne

1. Historical Notes on the Topf & Söhne Company
2. The Topf Cremation Furnaces for Civilian Use
   2.1. The Cremation Furnace with a Coke-Fed Gasifier
   2.2. The Gas-Fired Cremation Furnace
   2.3. The Cremation Furnace with Electrical Heating
3. The Topf Patents of the 1920s and 1930s
4. Topf Waste Incinerators
5. Topf Cremation Furnaces for Concentration Camps
   5.1. The Coke-Fired Cremation Furnace with One Muffle
   5.2. The Oil-Fired Mobile Cremation Furnace with Two Muffles
   5.3. The Coke- or Oil-Fired Cremation Furnace with Two Muffles

5.4. The Coke-Fired Cremation Furnace with Two Muffles Placed Opposite Each Other
6. The Topf Co. and the Construction of the Cremation Furnaces at Auschwitz-Birkenau
6.1. The Furnaces of Crematorium I at Auschwitz
6.2. The Furnaces of Crematoria II and III at Birkenau
6.3. The Furnaces of Crematoria IV and V at Birkenau
7. Structure and Operation of the Topf Cremation Furnaces at Auschwitz-Birkenau
7.1. The Coke-Fired Double-Muffle Furnace Auschwitz Type
7.2. The Coke-Fired Triple-Muffle Furnace
7.3. The Coke-Fired 8-Muffle Furnace
7.4. The Plans for Mass Cremations at Auschwitz-Birkenau
8. The Duration of the Cremation Process in the Topf Furnaces at Auschwitz-Birkenau
8.1. The Documents
8.2. Richard Kessler's Cremation Experiments
8.3. The List of Cremations in the Gusen Crematorium
8.4. The List of Cremations at the Westerbork Crematorium
8.5. Conclusions
9. The Cremation Capacity of the Cremation Furnaces at Auschwitz-Birkenau
9.1. Continuous Operation of the Furnaces
9.2. Concurrent Cremation of Several Corpses
9.3. Soviet and Polish Technical Investigations
9.4. Maximum Theoretical Cremation Capacity
9.5. Normal Cremation Capacity
9.6. Discussion of the *Zentralbauleitung* Letter of 28 June 1943
9.7. The Durability of Refractory Lining
9.8. The Effective Equivalent Operating Time of the Birkenau Cremation Furnaces
9.9. The Auschwitz-Birkenau Crematoria in the General Operation of the Camp
10. Heat Balance of the Topf Furnaces at Auschwitz-Birkenau
10.1. Remarks on the Method Used
10.2. Technical Data
10.3. Heat Balance of the Double-Muffle Furnace at Gusen
10.4. Heat Balance of the Double-Muffle Furnace at Auschwitz
10.5. Remarks on the Heat Balance
10.6. Heat Balance of the Topf Triple-Muffle Furnace
10.7. Heat Balance of the Topf 8-Muffle Furnace
10.8. Observations on the Coke Consumption of the Triple- and 8-Muffle Furnaces
10.9. A Comparison with the Kori Furnace at the Westerbork Camp and the Kori Slaughterhouse Furnaces
10.10. Some Thermal Aspects of the Triple-Muffle Furnace
10.11. On Claims of Flaming Chimneys
11. The Cremation Furnaces Built by Other German Companies: Kori, Ignis-Hüttenbau and Didier
11.1. Historical Remarks Concerning the H. Kori Co. of Berlin
11.2. The Coke-Fired Kori Cremation Furnaces for the Concentration Camps

11.3. The Oil-Fired Kori Cremation Furnaces for the Concentration Camps
11.4. The Oil-Fired Cremation Furnaces Built by Ignis-Hüttenbau A.G. at the Terezín Crematorium
11.5. The Didier Cremation Furnaces for Concentration Camps
11.6. Comparison of the Designs by Kori, Ignis-Hüttenbau, Didier and Topf
12. The Topf Furnaces and Regulations on Cremations in Greater Germany at the Outset of World War II

Appendices

1. Tables
   1.1. List of Cremations at the Westerbork Crematorium
   1.2. List of Cremations at the Terezín Crematorium
   1.3. Summary of the Topf Company's Activities at Auschwitz-Birkenau
   1.4. Patents (and Patent Applications) by J.A. Topf & Söhne
   1.5. Patent Applications by Department "DE" of J.A. Topf & Söhne
2. Glossary
3. Symbols
4. Abbreviations of Archive Names
5. Bibliography
   5.1. Alphabetical Listing
   5.2. Subject Listing
6. Indices
   6.1. Names
   6.2. Concentration Camps
   6.3. Crematorium Locations (Civilian)

Part 2: Documents (this book)

page

List of Documents 9
I. Civilian Cremation Furnaces 31
II. TOPF, Civilian Activities 150
III. TOPF, Correspondence with the SS 263

Part 3: Photographs (separate book)

I. Photographs 1-35: Gusen
II. Photographs 36-50: Dachau
III. Photographs 51-85: Mauthausen
IV. Photographs 86-110: Auschwitz Main Camp
V. Photographs 111-215: Buchenwald
VI. Photographs 216-235: Auschwitz-Birkenau
VII. Photographs 236-332: Kori Cremation Furnaces
VIII. Photographs 335-344: Kori Furnaces in Other Camps
IX. Photographs 345-362: Terezín
X. Photographs 363-365: Urns

XI. Photographs 366-367: Stoking Tools
XII. Photographs 368-370: Cremation Experiments
XIII. Color Documents from Part 2

Der Sarg ist zu bemessen (Abb. 12)
mit einer äusseren maximalen Breite von 750 mm
„ „ „ „ Höhe „ 720 „
„ „ „ „ Länge „ 2250 „

Verschiedene Krematorien-Verwaltungen bestimmen sogar nur:
die äussere maximale Höhe zu 700 und 650 mm und
„ „ „ Länge „ 2000 mm,
welche Maße aber als zu knapp anzusehen sind.
Man kann Holz- und Metallsärge verwenden.

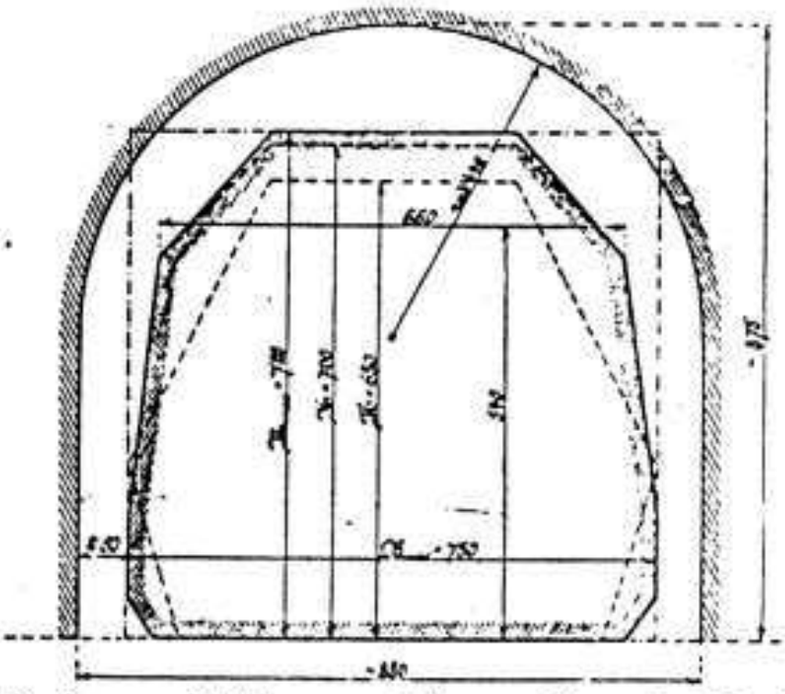

Abb. 12. Sarg- und Verbrennungskammerprofile; grösste Sarglänge 2250 mm, mittlere Kammerlänge 2500 mm.

Zur Erleichterung des Verbrennungsprozesses soll der Holzsarg aus leichtem Holz wie von Tanne oder Pappel hergestellt werden. Die Stärke der Holzbretter kann betragen:
höchstens 18 mm für den Unterteil und
„ 15 „ „ „ Deckel.

Zum Zusammenfügen der Bretter sind keine Nägel, sondern Holzpflöcke von ebensolchem weichen Holze zu verwenden; auch sind Metallbeschläge fortzulassen.

Metallsärge sollen aus 1 mm starkem Zinkblech vorfertigt werden. Um während des Transportes Deformationen

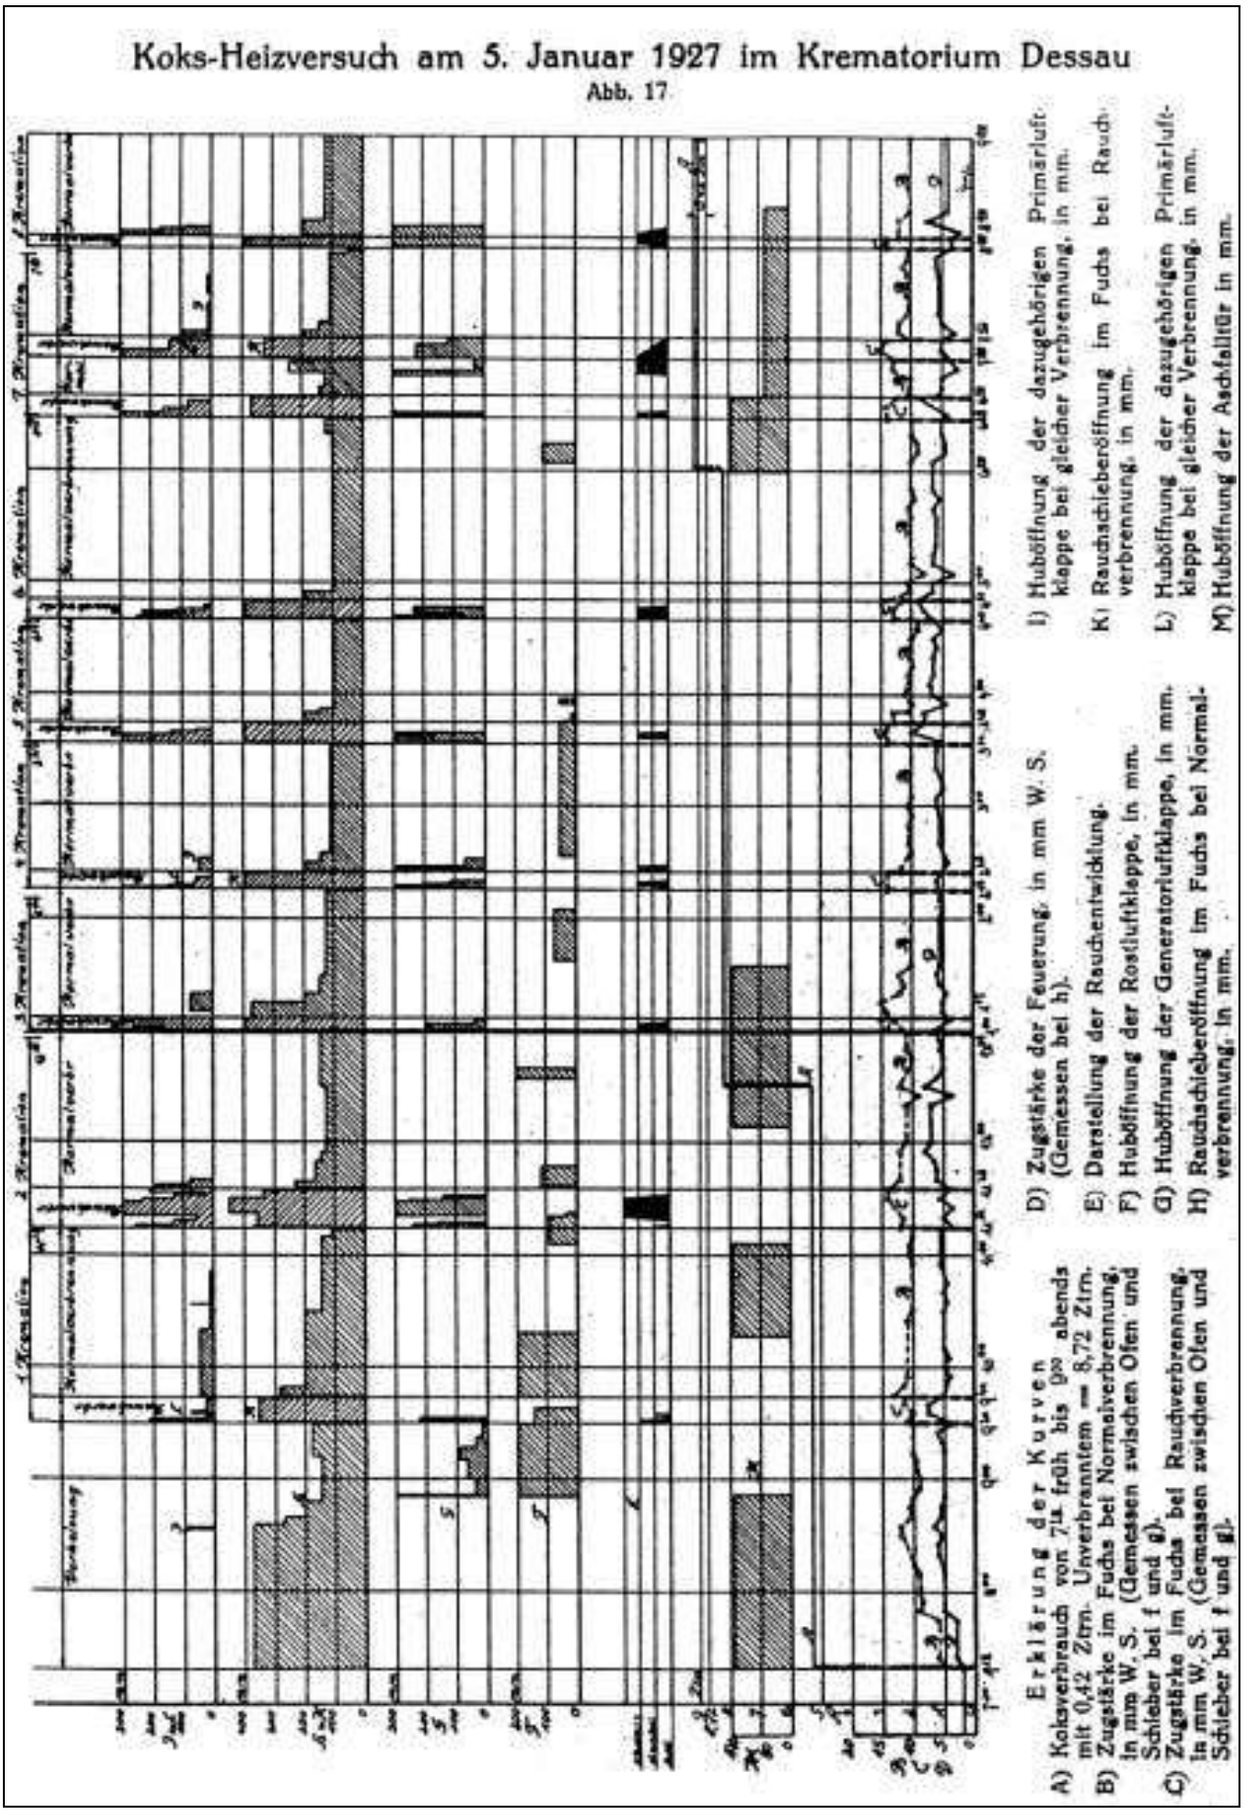
10 Muffle grate
11 Inclined plane of post-combustion chamber
12f. Lateral upper left-hand channel connecting the post-combustion chamber to the recuperator (12: inlet; 13: outlet)
14 Recuperator
15 Discharge channel for the smoke combustion and smoke valve
16 Discharge channel for normal combustion and normal valve
17 Flue duct
18 Chimney
19 Ash-chamber door (to take out the ashes of the corpse)
20 Adjustable air vent for normal combustion
21 Adjustable air vent for combustion of smoke
a Measuring point for muffle temperature (°C)
b Measuring point of discharge gas temperature (°C) during normal combustion and of primary air temperature (°C) during combustion of smoke in lateral upper-right-hand channel
c Measuring point of primary air temperature (°C) during normal combustion and of discharge-gas temperature (°C) during combustion of smoke in lateral upper-left-hand channel
d Measuring point of temperature of gasifier air
e Measuring point of temperature of discharge gas (°C) in flue duct
f Measuring point of draft in normal combustion
g Measuring point of draft in combustion of smoke
h Measuring point of draft in hearth



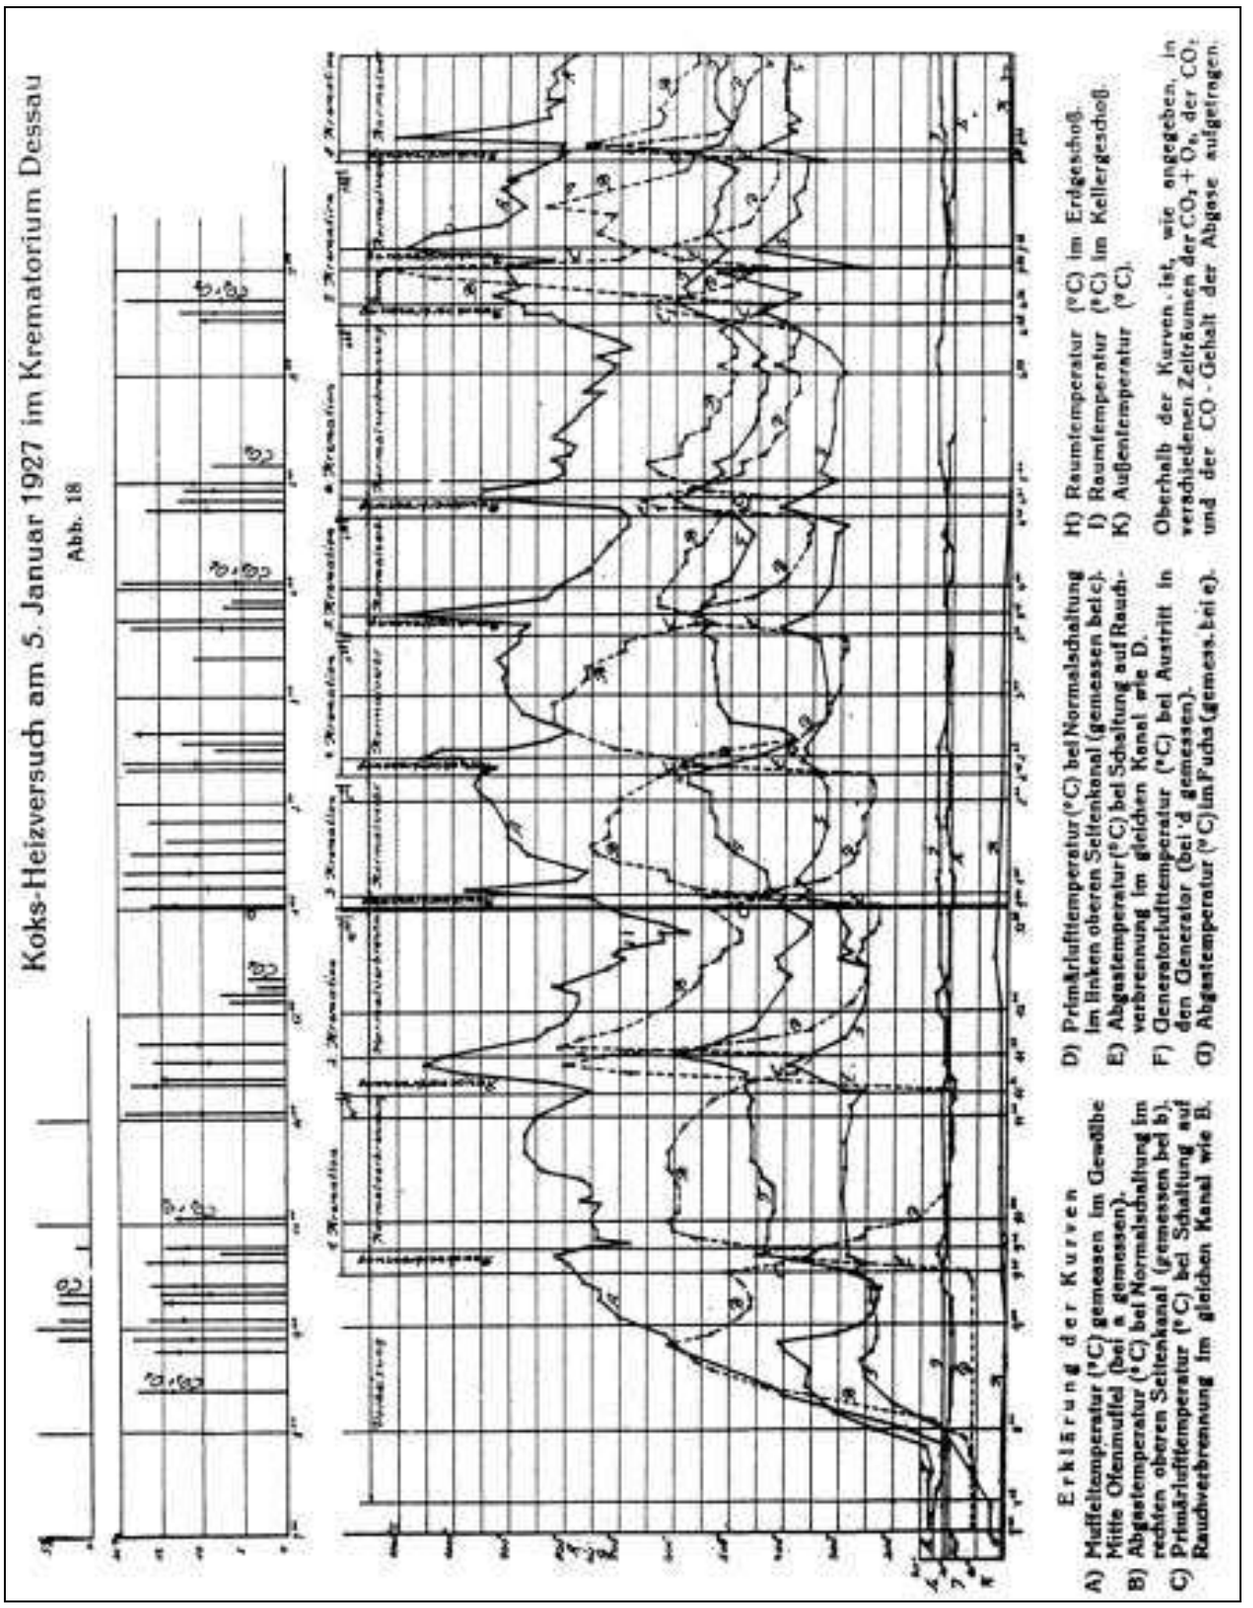
Document 47: as above. Cremation experiment with coke, conducted on 5 January 1927 by Engineer R. Kessler. Chart of furnace condition. Source: as Doc. 42, no. 9, p. 154.

The horizontal gives the duration of the various phases of the preheating (Vorheizung) of the furnace and of the subsequent eight cremations, for each one of which is

shown the combustion of smoke (Rauchverbrennung) and the normal combustion.
The vertical axis shows the measured property (from bottom to top):

0-20 Pressure difference in mm water column (= 0.1 mbar)
1-9 Zentner (= 50 kg) of coke loaded into gasifier
A Consumption of coke between 7:18 a.m. and 9 p.m. with 0.42 Zentner of incombustibles: 8.72 Zentner (= 436 kg)
B Draft in the flue duct during normal combustion, in mm water column (measured between the furnace and the damper at f *and at* g*)*
C Draft in the flue duct during combustion of smoke, in mm water column, (measured between the furnace and the damper at f *and at* g*)*
D Draft of the hearth, in mm water column (measured at h*)*
E Indication of type of smoke (hell: light, dunkel: dark, schwarz: black)
F Opening of air vent for air feed to hearth, mm
G Opening of air vent for air feed to gasifier, mm
H Opening of smoke damper in flue duct during normal combustion, mm
I Opening of the corresponding smoke damper during same combustion, mm
K Opening of smoke damper during combustion of smoke, mm
L Opening of corresponding air vent of primary air during same combustion, mm
M Opening of ash-chamber door (hearth), in mm

The above figures refer to the vertical cross section of the corresponding openings and dampers



Document 48: as Doc. 47. Temperature chart. Source: as Doc. 42, no. 9, p. 155.

The horizontal axis gives the duration of the various preheating and cremation phases, as in the previous chart. The vertical axis shows the temperatures:

- *A Temperature of the muffle (°C) measured in the center of the vault of the muffle of the furnace (measured at a).*
- *B Temperature of the discharge gas (°C) in normal mode, in the lateral upper right-hand channel (measured at b).*
- *C Temperature of primary air (°C) during smoke combustion mode, in the same channel as in B.*
- *D Temperature of primary air (°C) during normal mode in lateral upper left-hand channel (measured at c).*

E Temperature of discharge gas (°C) during smoke combustion mode, in the same channel as in D.
F Temperature of gasifier air (°C) at outlet of gasifier (measured at d).
G Temperature of discharge gas (°C) in flue duct (measured at e).
H Room temperature (°C) on ground floor.
I Room temperature (°C) in basement.
K Outside temperature (°C).
Above the temperature chart, we have indicated the $CO_2 + O_2$ content, the CO_2 content and partly the CO content at various times of the preheating and cremation phases.

überliegenden Seite der Ofenwand in einem außen abgeschlossenen Gehäuse eine elektrische Birne an, deren in den Ofen geworfene Lichtstrahlen durch eine vorgebaute Linse verstärkt werden.

Abschließend sei noch auf das Beobachtungsfenster von Mahon hingewiesen. Dasselbe ist mit einer dauernd und unmittelbar der Wärmestrahlung des Ofens ausgesetzten feuerfesten Scheibe versehen, wobei nicht nur die betreffende Scheibenoberfläche, sondern auch die dem Ofeninnern zugewandten Scheibenkanten vollständig oder doch mit nur geringen Unterbrechungen der Wärmestrahlung unterliegen. Dadurch soll eine ungleichmäßige Erwärmung der Scheibe und das damit verbundene Auftreten von Wärmespannungen, insbesondere an den Rändern der Scheibe vermieden werden. Die Befestigung der Scheibe an der dem Ofeninnern zugewandten Seite erfolgt statt durch die sonst üblichen Leisten — wie Abb. 5 zeigt — mittels schmaler, aus dem Rahmen vorspringender Flachen, die sich nur auf kleine Teile der unmittelbar bestrahlten Scheibenoberfläche gewissermaßen punktförmig auflegen. Die Scheiben können auch durch die Rahmenfläche selbst gehalten werden, indem diese unter einem spitzen Winkel zur unmittelbar bestrahlten Scheibenoberfläche gestellt werden und so die dem Ofeninnern zugewandten Scheibenkanten lediglich berühren, aber nicht überdecken (Abb. 6). Das Mahonsche Beobachtungsfenster besteht aus zwei halbathermanen Glasplatten und aus einer zwischen diesen mit Abstand angeordneten gefärbten Glasplatte. Letztere ist aus mehreren Glasstreifen zusammengesetzt, wobei die aneinanderstoßenden Streifenkanten schiefwinklig abgeschrägt sind. Durch eine solche Unterteilung wird die Oberflächenspannung verringert. Gleichzeitig werden etwa auftretende Verzerrungen in der Scheibe ausgeglichen, ohne daß sich dabei in der Scheibe Spalte bilden können. [249]

Die neuzeitlichen Leicheneinäscherungsöfen mit Koksfeuerung, deren Wärmebilanz und Brennstoffverbrauch.

Von Wilhelm Heepke, Mittweida.

Mit sechs Abbildungen.

Inhaltsangabe: Entwicklung der Feuerbestattung. Bisheriges feuerungstechnisches Schrifttum. Direkte und indirekte Einäscherung; Regeneratoren und Rekuperatoren. Schwierigkeiten für die Berechnung, starke Temperaturschwankungen. Der Koksofen mit Rekuperator. Wärmebedarfsmengen, Wärmegewinne, Wärmeverluste, Brennstoffaufwand. Die Erhebungsgebühr für eine Einäscherung.

(Schluß von Seite 111.)

Einen Überblick über das Ineinandergreifen der verschiedenen Verbrennungsprozesse gibt das Wärmediagramm Abb. 2, dessen Zahlenwerte in der späteren Entwicklung ihre Erklärung finden. Die verschiedenen Wärmebeträge W, die sich durch den Einäscherungsprozeß ergeben, sind in Abb. 2 als Prozentverhältnisse des Brennstoffnutzeffektes verrechnet und durch die strichpunktierten Linien markiert. Für den ersten Koksverbrennungsprozeß kommen die Wärmeverluste mit voller Liniensignatur in Frage.

Sieht man von dem alten Gothaer Ofen ab, der zudem zuerst mit böhmischer Braunkohle gefeuert wurde, so kommt als neuzeitliche Bauart nur der Koksofen mit Rekuperator in Betracht; letzterer ist aus Schamottesteinen aufgebaut. Die ersten Beck-Öfen der 90er Jahre waren nach dem Klingenstierna-System mit gußeisernen Luftrekuperatorröhren ausgerüstet. Bemerkenswert ist hierfür, daß in der Eisenhüttenindustrie zur Zeit wieder eine Neigung zur Verwendung von Metallröhrenrekuperatoren vorliegt. In der neuesten Beckschen Bauart Abb. 3 ist die Zerlegung der bisherigen Rechtecks-Rekuperatorkanäle in patentierte Dreiecksquerschnitte c_1 und c_2 beachtenswert, ebenso auch die Vergrößerung der Rauchgaskanalquerschnitte c_3 auf Kosten der Luftkanalquerschnitte c_4 bei dem Didier-Ofen Abb. 4. Diese Maßnahmen gehen darauf hinaus, die Kanalquerschnitte den Durchflußmengen und besonders

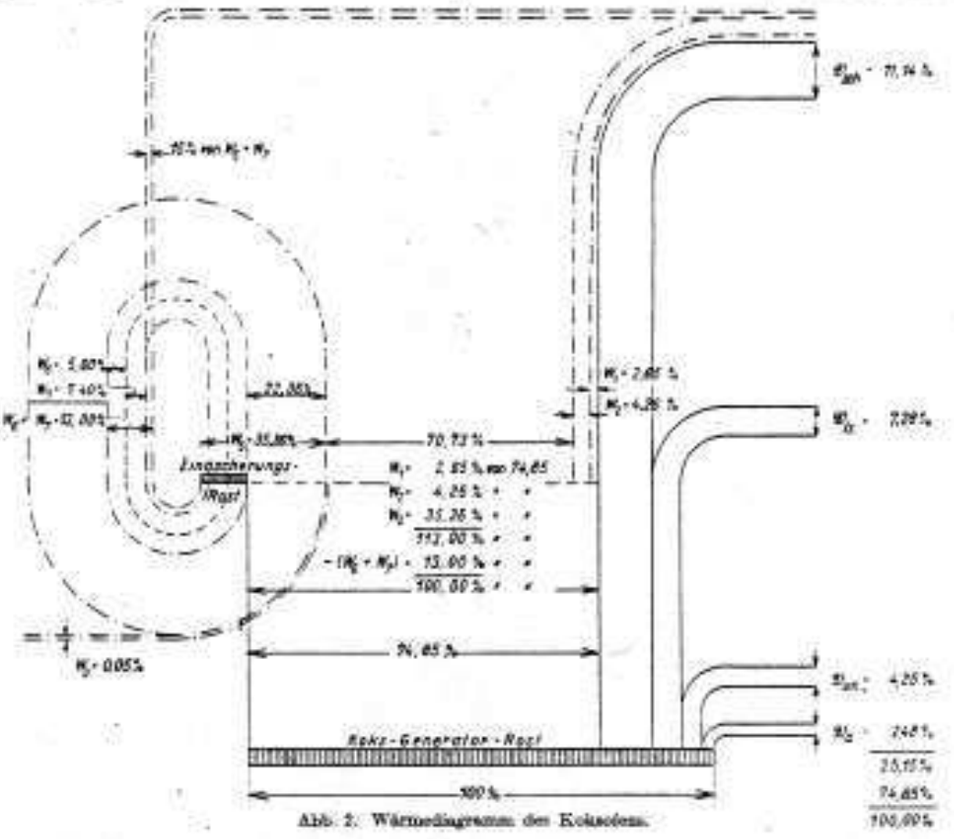

Abb. 2. Wärmediagramm des Koksofens.

Document 91: Article by engineer Wilhelm Heepke, "Die neuzeitlichen Leicheneinäscherungsöfen mit Koksfeuerung, deren Wärmebilanz und Brennstoffverbrauch", in: Feuerungstechnik*, XXI. Jg., 15 August 1933, no. 8, pp. 123-128.*

den anfallenden großen Rauchgasmengen zwecks Vernichtung des Rauches genauer anzupassen. Durch den Beckschen Dreiecksrekuperator werden Lufterhitzungen bis 600° und mehr erzielt. Als weitere Neuerung ist die Anbringung mehrfacher Kanalmündungen für die Leichenverbrennungsluft in dem Deckengewölbe der Sargmuffel anzusehen.

Der Beck-Ofen hat den Vorzug, daß die Feuergase von vorn nach hinten gezogen werden. Beim Öffnen des Hauptschiebers zur Einführung des Sarges können also keine Gase

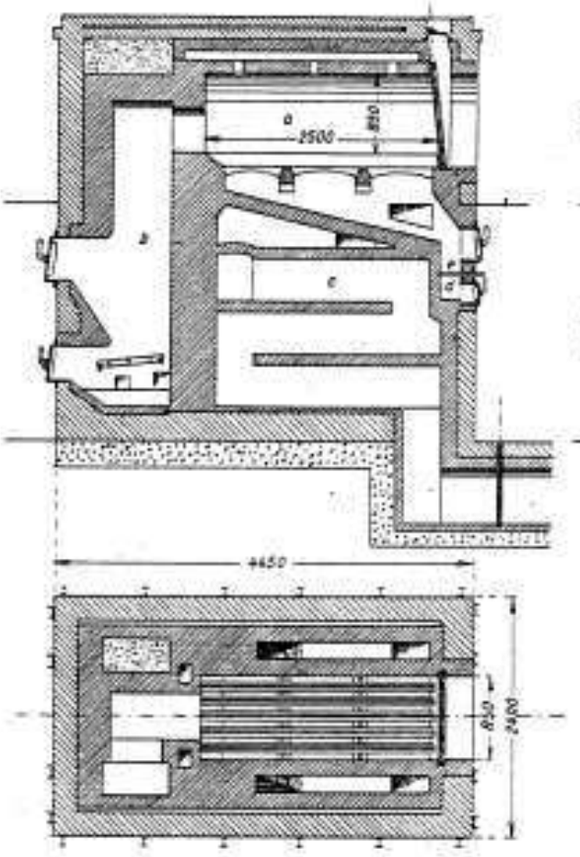

Abb. 3. Beck-Koksofen mit Dreiecksrekuperator.
a = Einäscherungsmuffel, b = Kompensator, c = Rekuperator, d_1 = Rauchgaskanäle, d_2 = Luftkanäle, d = Leichenaschen-Sammelraum, e = Kaminverbindungszug.

in den Heizraum austreten. Ist die Asche auf die unter dem Sargrost liegende schiefe Ebene gefallen und noch mit einigen brennbaren Teilen durchsetzt, so wird sie auf den Nachverbrennungsrost e gezogen, wo sie in sich restlos verbrennt. Hiernach wird dieser Rost gekippt, infolgedessen die Asche in den darunter befindlichen Aschenbehälter d fällt. Der Didier-Ofen ist eine für größere Krematorien und für Dauerbetrieb vorgesehene schwere Ofenbauart. Für Anstalten mit nur wenigen Einäscherungen in der Woche wird der Ofen in seinem Unterbau durch Fortlassen von ein oder zwei Rekuperatorzügen niedriger gehalten, wodurch das Anheizen schneller vor sich geht. Man hat bei den Didier-Öfen ferner die Möglichkeit, die aus der Muffel a abziehenden Feuergase vor Eintritt in den Rekuperator c noch mit durch die Heizzüge der Muffel leiten zu können und so an Brennstoff für das Aufheizen der Muffel a für die Einäscherung der nächsten Leiche zu sparen. Durch die Trennung von Generator b und Muffel a ist die Feuerführung für das Anwärmen der Muffel so gehalten, daß Abgase aus der Feuerung während der Einäscherung selbst in den Einäscherungsraum nicht gelangen können.

Um nun zu einer Rechnung zu kommen, müssen von Schwankungen der Wärmemengen und Temperaturen abgesehen, nur bestimmte Normal-, Maximal- oder Minimalwerte, wie sie passend erscheinen, zugrunde gelegt werden.

Das Gewicht der Leiche einer erwachsenen Person kann 70÷100 kg betragen. Hiervon entfallen 65% auf den Wassergehalt und somit 35% auf die Trockensubstanz, von der 5% Unverbrennbares (Asche) sind. Die 35 — 5 = 30% brennbare Substanz setzt sich zusammen aus 12% Fett, 15% Eiweißstoffen und 3% sonstigen chemischen Stoffen oder aus 52% C, 7% H, 22% O, 1% S und 17% N. Danach erhält man bei Voraussetzung eines mittleren Leichengewichtes von 0,5 (70 + 100) = 85 kg als brennbares Leichengewicht 0,3 · 85 = 25,5 kg, welches besteht aus:

0,12 · 85 = 10,20 kg Fett
0,15 · 85 = 12,75 kg Eiweiß
0,03 · 85 = 2,55 kg Sonstiges
25,50 kg

oder:

c = 0,52 · 25,5 = 13,260 kg C
h = 0,07 · 25,5 = 1,785 kg H
o = 0,23 · 25,5 = 5,865 kg O
s = 0,01 · 25,5 = 0,255 kg S
n = 0,17 · 25,5 = 4,335 kg N
25,500 kg

Für eine derartige brennbare Masse, die in ihrer Zusammensetzung einem festen Brennstoff gleichkommt, besteht eine Luftüberschußzahl $m = \frac{20,5}{CO_2}$. Nach praktischen Messungen kann $CO_2 = 13\%$ gesetzt werden, somit $m = \frac{20,5}{13} = 1,5$.

Zur vollkommenen Verbrennung dieser Bestandteile ist eine wirkliche Verbrennungsluftmenge nötig von:

$$L = m \cdot \frac{2,67c + 8h - s - o}{0,30}$$
$$= 1,5 \cdot \frac{2,67 \cdot 13,260 + 8 \cdot 1,785 + 0,255 - 5,865}{0,30}$$
$$= 220,365 = \sim 220 \text{ m}^3 \text{ von } 0° \text{ und } 760 \text{ mm}.$$

Die Temperatur t in der Sargmuffel soll erfahrungsgemäß und auf Grund von genauen Versuchen nicht unter ~ 800° sinken und nicht über 1000° steigen, damit eine möglichst vollkommene Verbrennung und völlig ausgeglühte weiße Asche gewonnen wird. Bei $t > 1000°$ würde zwar die Verbrennung rascher vor sich gehen, dagegen würden aber die Knochen schwarz und hart werden. Es soll daher $t = 900°$ angenommen werden.

Die Luft wird im Rekuperator von der Anfangs- oder Raumtemperatur $t_0 = 10°$ auf $t_1 = 350°$ vorgewärmt. Es wird dabei $t = 350°$ vorausgesetzt, da die Entzündungstemperatur des Sargholzes bei 325—350 liegt. Es ist dann für die Luft noch eine Wärmemenge vorzusehen von:

$$W_1 = 0,31 \cdot L \cdot (t - t_1) = 0,31 \cdot 220\,(900 - 350)$$
$$= 37\,510 = \sim 38\,000 \text{ kcal}.$$

Die in der Leiche enthaltene 65proz. Wassermenge von $g = 0,65 \cdot 85 = 55,25$ kg ist ebenfalls auf $t = 900°$ zu bringen, das heißt in Sattdampf von 100° zu verwandeln und danach bis auf 900° zu überhitzen. Mit einer Erzeugungswärme $i = 640$ kcal/kg bei 1 ata und $c_p = 0,48$ spez. Überhitzungswärme ergibt sich ein für diese Wasserverdampfung erforderlicher Wärmeaufwand von:

$$W_2 = g \cdot [i + c_p (t - t_0)] = 55,25\,[640 + 0,48\,(900 - 10)]$$
$$= 58\,963 = \sim 60\,000 \text{ kcal}.$$

Document 91: continued

Jahrgang 83, 1939 H. Treptau, Die deutschen Leichenverbrennungsöfen mit Koksfeuerung usw. 125

Das Unverbrennbare, die 5% Knochen von $0{,}05 \cdot 85 = 4{,}25$ kg Gewicht, wird während des Einäscherungsprozesses bei 0,2 spez. Wärme eine Wärmemenge:

$$W_3 = 0{,}2 \cdot 4{,}25\,(900 - 10) = 740{,}5 = \sim 800 \text{ kcal}$$

binden, die mit Herausnahme der Asche aus dem Sammelbehälter als Verlust zu buchen ist.

Das Schamottefutter des Oberbaues des Ofens mit Muffel, Rost, Kanälen und Aschesammelraum kann mit ~ 3 m³ angenommen werden, besitzt also bei 1800 kg/m³ spez. Gewicht ein Gewicht $G_1 = 3 \cdot 1800 = 5400$ kg. Die Temperatur dieses Schamottemauerwerkes beträgt nach Meßversuchen etwa $\vartheta = 800°$, so daß bei einer spez. Wärme von 0,21 für die Erwärmung dieses Ofenoberteiles von 10° auf 800° aufzubringen sind:

$$W_1 = c_p \cdot G_1\,(\vartheta - t_0) = 0{,}21 \cdot 5400 \cdot (800 - 10) = 895\,860 = \sim 900\,000 \text{ kcal}.$$

Der untere Ofenteil mit dem Rekuperator umfaßt ~ 4 m³ Schamottemauerwerk, hat also ein Gewicht von $G_2 = 4 \cdot 1800 = 7200$ kg. Unter Voraussetzung ungünstig niedriger Verhältnisse treten die Heizgase mit $T_1 = 600°$ in den Rekuperator und verlassen ihn durch den Fuchs mit $T_2 = 200°$. Hiermit sind gegeben:

die mittlere Rauchgastemperatur zu:

$$T_m = \frac{T_1 + T_2}{2} = \frac{600 + 200}{2} = 400°,$$

die mittlere Lufttemperatur zu:

$$t_m = \frac{t_0 + t_1}{2} = \frac{10 + 350}{2} = 180°.$$

Mit $s = {}^1/_2$ Schamottestein der Rekuperatorwände, also $= 0{,}065$ m Stärke;
$\lambda =$ Wärmeleitzahl der Schamottesteine, $= 0{,}60$ bei $400 \div 500°$;
$\alpha =$ Wärmeübergangszahl für rauhe Wandoberfläche, $= 9{,}0$ bei $v \leqq 5$ m/s Geschwindigkeit (nach Jürges)

wird die Warmedurchgangszahl der Rekuperatorwände:

$$k = \frac{1}{\frac{1}{\alpha} + \frac{s}{\lambda} + \frac{1}{\alpha}} = \frac{1}{\frac{1}{9} + \frac{0{,}065}{0{,}6} + \frac{1}{9}} = \frac{1}{0{,}33} = 3.33 \text{ kcal/m}^2\,°\text{C h}.$$

Damit erhält man die beiden Oberflächentemperaturen der Rekuperatorsteine zu:

$$\vartheta' = T_m - (T_m - t_m)\frac{k}{\alpha} = 400 - (400 - 180)\frac{3.33}{9} = 318°,$$

$$\vartheta'' = t_m + (T_m - t_m)\frac{k}{\alpha} = 180 + (400 - 180)\frac{3.33}{9} = 262°,$$

und die mittlere Steintemperatur:

$$\vartheta_m = \frac{\vartheta' + \vartheta''}{2} = \frac{318 + 262}{2} = 290°.$$

Da $\alpha = \alpha' = \alpha'' = 9{,}0$ gesetzt ist, so muß auch sein:

$$\vartheta_m = \frac{T_m + t_m}{2} = \frac{400 + 180}{2} = 290°.$$

Mit $\vartheta_m = \sim 300°$ sind dann für die Anwärmung des Rekuperators erforderlich:

$$W_2 = c_p \cdot G_2 \cdot \vartheta_m = 0{,}21 \cdot 7200 \cdot 300 = 453\,600 = \sim 454\,000 \text{ kcal},$$

die zur Erhöhung der Lufttemperatur von 10° auf 350° dienen.

Da nun die Ofentemperatur über der Entzündungstemperatur des Sargmateriales liegt, so werden bei Einführen des Sarges dieser wie auch danach die Leiche unter Einwirkung der heißen Luft bzw. deren Sauerstoffes alsbald zur Verbrennung kommen.

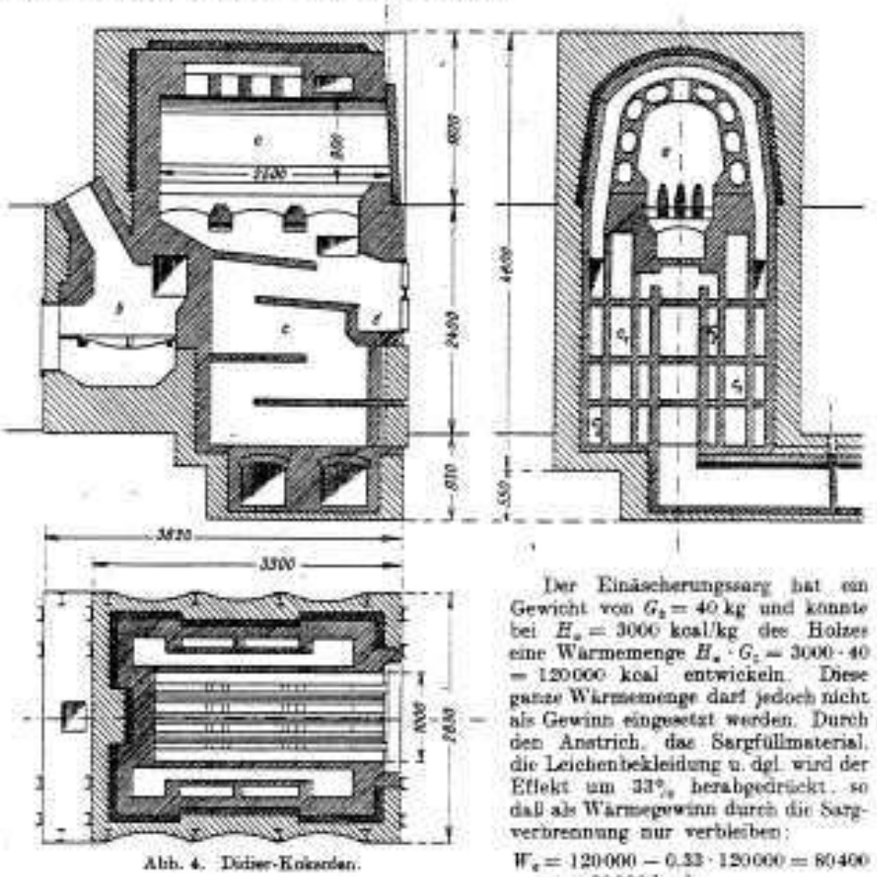

Abb. 4. Didier-Koksofen.

Der Einäscherungssarg hat ein Gewicht von $G_3 = 40$ kg und könnte bei $H_u = 3000$ kcal/kg des Holzes eine Wärmemenge $H_u \cdot G_3 = 3000 \cdot 40 = 120\,000$ kcal entwickeln. Diese ganze Wärmemenge darf jedoch nicht als Gewinn eingesetzt werden. Durch den Anstrich, das Sargfüllmaterial, die Leichenbekleidung u. dgl. wird der Effekt um 33% herabgedrückt, so daß als Wärmegewinn durch die Sargverbrennung nur verbleiben:

$$W_4 = 120\,000 - 0.33 \cdot 120\,000 = 80\,400 = \sim 80\,000 \text{ kcal}.$$

Da die brennbare Substanz der Leiche aus denselben organischen Bestandteilen besteht wie ein fester Brennstoff, so läßt sich die bei der Verbrennung der Leiche entwickelte Wärmemenge nach der üblichen Verbandsformel bestimmen zu:

$$W_5 = 8100 \cdot c + 29\,000\left(\lambda - \frac{o}{8}\right) + 2500\,s - 600 \cdot \varrho$$

$$= 8100 \cdot 13.26 + 29\,000\left(1{,}785 - \frac{5{,}865}{8}\right) + 2500 \cdot 0{,}255 - 600 \cdot 55{,}25 = 105\,402 \text{ kcal}.$$

Rechnet man mit dem Fettbestandteil der Leiche und nimmt den Heizwert des Fettes mit 8000 kcal/kg und den der Eiweiß- und übrigen Stoffe mit 1500 kcal/kg an, so erhält man:

$$W_5 = 8000 \cdot 10{,}2 + 1500\,(12{,}75 + 2{,}55) = 104\,550 \text{ kcal}.$$

Man kann aber auch zur Ermittlung von W_5 bewährte Erfahrungswerte von tierischen Verbrennungsöfen heranziehen. In derartigen guten Öfen rechnet man mit einem Kohle- oder Koksverbrauch von $0{,}350 \div 0{,}375$ kg zum Verbrennen von

Document 91: continued

1 kg Fleisch in 1 Minute. Mit $\eta = 0{,}5$ und $H_u = 7000$ kcal/kg für Koks wird:

$$W_2 = 0{,}5 \cdot 7000 \cdot 0{,}350 \cdot 85 = 104\,125 \text{ kcal}.$$

Man kann mithin endgültig setzen:

$$W_2 = 105\,000 \text{ kcal}.$$

Für die Verbrennung einer 85-kg-Leiche ist also nach vorstehendem Erfahrungswert eine Verbrennungsdauer von 85 Minuten = 1 Stunde und 25 Minuten nötig. Dies ist eine Zeit, die auch in den neuzeitlichen Leichenein-äscherungsöfen vorauszusetzen ist.

Für eine erste Einäscherung mit Hochheizen des kalten Ofens erhält man nunmehr folgende Wärmebilanz:

Aufzuwendende Wärmemengen:

für Erwärmung der Einäscherungsluft	$W_1 =$	38 000 kcal
für Wasserverdampfung	$W_2 =$	60 000 „
für Eigenerwärmung der Asche	$W_3 =$	800 „
für Erwärmung des oberen Ofenteiles	$W_4 =$	900 000 „
für Erwärmung des unteren Ofenteiles	$W_5 =$	454 000 „
	$\sum (W_1 + W_5) =$	1 452 800 kcal

Erzeugende Wärmemengen:

durch Verbrennung d. Sarges	$W_6 =$ 80 000 kcal	
durch Verbrennung d. Leiche	$W_7 =$ 105 000 „	
	$W_6 + W_7 =$ 185 000 kcal	185 000 kcal
Somit liegt für eine erste Einäscherung ein Wärmebedarf vor		$W_r =$ 1 267 800 kcal

Als Brennstoff kommt Koks als Gas- oder Hüttenkoks in Frage. Für nachstehende Berechnung wird ein Zechenkoks zugrunde gelegt, dessen chemische Analyse ergeben hat:

C = 78,84; H = 0,51; O = 1,0; S = 0,91; W = 8,21; A = 10,53%.

Dafür findet sich der untere theoretische Heizwert zu:

$$H_u = 81\,C + 290\left(H - \frac{O}{8}\right) + 25\,S - 6\,W$$

$$= 81 \cdot 78{,}84 + 290\left(0{,}51 - \frac{1{,}00}{8}\right) - 25 \cdot 0{,}91 - 6 \cdot 8{,}21$$

$$= 6471{,}18 = \sim 6470 \text{ kcal/kg}.$$

Zur Bestimmung des Nutzeffektes bzw. Wirkungsgrades ζ sind die Wärmeverluste des Ofens zu erfassen, die sich aus dem Schornsteinverlust, den Verlusten durch Leitung und Strahlung, durch unvollkommene Verbrennung und durch Herdrückstände (Asche) zusammensetzen. Für diese Ermittlung werden Zahlenwerte benutzt, die durch Versuche und Erfahrungen mit obigem Brennstoff gefunden wurden. Teilweise muß natürlich für diese Darstellung auf Mittelwerte zugekommen werden. Gefunden wurden: die Fuchstemperatur $T_F = 200°$, die Raumtemperatur beim Anheizen $t_0 = 10°$ und nach Inbetriebsetzen $t_0 = 20°$, die Analysenwerte des Heizgases (Rauchgases) $CO_2 = 13$, $O_2 = 7{,}3$, $CO = 0{,}5$, $H_2 = 0{,}4$, $CH_4 = 0{,}3$ und $N = 70{,}5$ Vol.-%, die Koksaschenmenge einer ersten Heizung $A' = 12$ kg mit Analysenwerten $C_a = 47{,}8$, $H_a = 0{,}1$, $S_a = 1{,}6$ und Unverbrennlichem 50,5%, also Unverbranntes und noch Brennbares in der Asche: $U_a = (C_a + H_a + S_a) = 47{,}8 + 0{,}1 + 1{,}6 = 49{,}5\%$.

Der Heizwert von U_a war nach der Verbrennungsuntersuchung in der Berthelot-Mahlertschen Bombe $H_{ua} = 3650$ kcal/kg.

Hiermit erhält man als Schornsteinverlust:

$$\mathfrak{V}_{sch} = \left[0{,}32\,\frac{C}{0{,}536 \cdot CO_2} + 0{,}0048\,(9\,H + W)\right](T_F - t_0)\cdot\frac{100}{H_u}$$

$$= \left[0{,}32\,\frac{78{,}84}{0{,}536 \cdot 13} + 0{,}0048\,(9 \cdot 0{,}51 + 8{,}21)\right](200 - 10)\,\frac{100}{6470}$$

$$= 10{,}80\%.$$

Oder mit dem Volumen der trockenen Verbrennungsgase:

$$R_r = \frac{0{,}01 \cdot C}{0{,}536\,\frac{CO_2 + CO + CH_4}{100}} = \frac{0{,}01 \cdot 78{,}84}{0{,}536\,\frac{13 + 0{,}5 + 0{,}3}{100}}$$

$$= 10{,}7 \text{ m}^3/\text{kg}$$

und der mittleren spez. Wärme der Rauchgase:

$$c_{pm} = 0{,}318 + 0{,}000046\,(T_F - t_0) = 0{,}318 + 0{,}000046\,(200 - 10)$$

$$= 0{,}327.$$

zu:

$$\mathfrak{V}_{sch} = \frac{R_r \cdot c_{pm}\,(T_F - t_0)\cdot 100}{H_u} = \frac{10{,}7 \cdot 0{,}327\,(200 - 10)\cdot 100}{6470}$$

$$= 10{,}30\%.$$

Oder mit dem Luftüberschuß $m_1 = 1{,}5$ im Generator, dem Rauchgasgewicht:

$$R_r = 1{,}4\,\frac{m_1 H_u}{1000} = 1{,}4\,\frac{1{,}5 \cdot 6470}{1000} = 13{,}57 \text{ kg},$$

dem Ausstrahlungsverhältnis $\varepsilon = 0{,}15$, der spez. Wärme der Gase $c = \sim 0{,}24$ und dem Wirkungsgrad des Generators $\eta = \sim 0{,}90$, der Feuertemperatur zu:

$$T = t_0 + \eta_1\,\frac{H_u(1 - \varepsilon)}{R_r \cdot c}$$

$$= 10 + 0{,}90\,\frac{6470\,(1 - 0{,}15)}{13{,}57 \cdot 0{,}24}$$

$$= 1516 = \sim 1500°$$

und damit nach Abb. 5 mit den genaueren spez. Wärmen von $c = 0{,}282$ bei $T = 1500°$ und $c_F = 0{,}235$ bei $T_F = 200°$ zu:

$$\mathfrak{V}_{sch} = \frac{T_F \cdot c_F}{T \cdot c}\cdot 100$$

$$= \frac{200 \cdot 0{,}235}{1500 \cdot 0{,}282}\cdot 100$$

$$= 11{,}14\%.$$

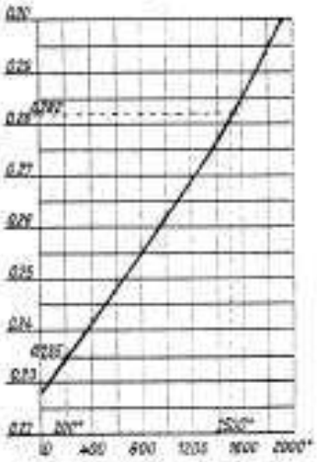

Abb. 5. Spezifische Wärme von 1 kg Rauchgas bei $m = 10\%$. (Nach Dr. Bansen, Stahl und Eisen 1913.)

Oder schließlich nach Siegert zu:

$$\mathfrak{V}_{sch} = 0{,}70\,\frac{T_F - t_0}{CO_2} = 0{,}70\,\frac{200 - 10}{13} = 10{,}50\%.$$

Der Verlust durch unverbrannte Gase (unvollkommene Verbrennung) entsteht durch den Gehalt der Abgase an Unverbranntem als CO und CH_4 und ist bestimmt zu:

$$\mathfrak{V}_{un} = \frac{R_r\,(3030 \cdot CO + 2580\,H_2)}{H_u} = \frac{10{,}7\,(3053 \cdot 0{,}5 + 2580 \cdot 0{,}4)}{6470}$$

$$= 4{,}25\%,$$

oder angenähert nach Brause zu:

$$\mathfrak{V}_{un} = \sim\frac{70 \cdot (CO - H_2)}{CO_2 + CO + H_2} = \frac{70 \cdot (0{,}5 - 0{,}4)}{13 + 0{,}5 + 0{,}4} = 4{,}33\%.$$

Den Verlust durch Herdrückstände (Asche, Schlacke) erhält man mit obigen Angaben und mit einer vorläufigen Annahme des Brennstoffverbrauches (nach Erfahrungen) von $B = \sim 300$ kg zu:

$$\mathfrak{V}_a = U_a \cdot \frac{A' \cdot 8100}{B\,H_u} = 49{,}5 \cdot \frac{12}{300} \cdot \frac{8100}{6470} = 2{,}48\%.$$

Oder:

$$V_a = \frac{A' \cdot H_{ua} \cdot 100}{B \cdot H_u} = \frac{12 \cdot 3650 \cdot 100}{300 \cdot 6470} = 2{,}26\%.$$

Der Verlust durch Wärmeleitung und -strahlung des Ofens muß vielfach als Restglied in die Bilanzrechnung eingesetzt werden. Hier läßt er sich jedoch mit Hilfe der Wärmedurchgangsgleichung erfassen.

Der ganze freistehende Ofenmauerklotz besitzt eine Außenfläche von $F = 90$ m². Die mittlere Temperatur der Innenwände kann mit $\vartheta_i' = \frac{\vartheta + \vartheta_a}{2} = \frac{800 - 300}{2} = 550°$

Document 91: continued

eingesetzt werden. Für die Wärmedurchgangszahl gilt mit $\alpha_1 = \alpha_2 = 7$ (Innenwand) nach Abb. 6:

$$k = \frac{1}{\frac{1}{\alpha_1} + \frac{\delta_1}{\lambda_1} + \frac{\delta_2}{\lambda_2} + \frac{\delta_3}{\lambda_3} + \frac{1}{\alpha_2}} = \frac{1}{\frac{1}{7} + \frac{0{,}12}{0{,}70} + \frac{0{,}010}{0{,}60} + \frac{0{,}38}{0{,}45} + \frac{1}{7}}$$

$$= \frac{1}{1{,}317} = 0{,}76 \text{ kcal/m}^2\text{°Ch}.$$

In $z = 3$ Stunden Anheizzeit des Einäscherungsofens nach Erreichen des Generatorbeharrungszustandes ist der Wärmeverlust durch den Ofenmauerklotz:

$$W_v = k \cdot F (\vartheta'_m - t'_0) z = 0{,}76 \cdot 90 (550 - 20) \cdot 3 = 108\,756 \text{ kcal}$$

oder:

$$\frac{W_v \cdot 100}{B \cdot H_u} = \frac{108\,756 \cdot 100}{300 \cdot 6470} = 5{,}60\%.$$

Rechnet man hierzu noch 30% für die rechnerisch nicht zu erfassenden, aber immerhin bedeutenden Wärmeverluste

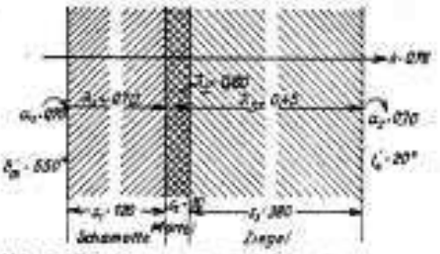

Abb. 6. Bestimmung der Wärmedurchgangszahl k.

durch Falschluft und Undichtigkeiten im Mauerwerk, in Klappen und Schiebern, so wird:

$$\mathfrak{V}_u = 1{,}3 \cdot 5{,}60 = 7{,}28\%.$$

Alle vorstehenden Prozentwerte der Wärmeverluste beziehen sich auf das Prozentverhältnis von H_u.

Mit dem Größtwerte der ermittelten Prozentsätze wird dann der Gesamtnutzeffekt (siehe auch Abb. 2):

$$100 - (\mathfrak{V}_{ast} + \mathfrak{V}_m + \mathfrak{V}_a + \mathfrak{V}_u) = 100 - (11{,}14 + 4{,}25 + 2{,}48 + 7{,}28)$$
$$= 100 - 25{,}15 = 74{,}85 = \sim 75\%$$

und der Wirkungsgrad:

$$\eta = 0{,}75,$$

also der wirkliche Heizwert des Kokses:

$$\eta H_u = 0{,}75 \cdot 6470 = 4850 \text{ kcal/kg}.$$

Für eine erste Einäscherung ist mithin der Brennstoffaufwand:

$$B_I = \frac{W_I}{\eta H_u} = \frac{1\,267\,800}{4850} = 262 \text{ kg}.$$

Für Öfen schwerer Bauart erhöhen sich G und G_1 und damit W_4 und W_1 derart, daß B_I auf 300–400 kg und mehr steigt.

Für eine zweite anschließende Einäscherung sind aufzubringen einmal die Wärmemengen für die Verbrennungsluftvorwärmung, Wasserverdunstung und Aschenabsorptionswärme mit:

$$W_1 + W_2 + W_3 = 38\,000 + 60\,000 + 800 = 98\,800 \text{ kcal},$$

dann $\sim 30\%$ für Deckung der Wärmeverluste des Ofens, hervorgerufen durch Absorption, Leitung, Strahlung, Falschluft, Sargeinführung, Klappen und Schieber usw., also:

$$0{,}30 (W_4 + W_5) = 0{,}30 (900\,000 + 454\,000) = 406\,200 \text{ kcal}.$$

Durch die Sarg- und Leichenverbrennung werden:

$$W_6 + W_7 = 80\,000 + 105\,000 = 185\,000 \text{ kcal}$$

erzeugt, von welcher Wärmemenge $\sim 15\%$ mit den Abgasen durch den Schornstein als Verlust entweichen.

Somit stehen zur Verfügung:

$$0{,}85 (W_6 + W_7) = 0{,}85 \cdot 185\,000 = 157\,250 \text{ kcal}.$$

Für die zweite Einäscherung sind also aufzubringen:

$$W_{II} = (98\,800 + 406\,200) - 157\,250 = 347\,750$$

und:

$$B_{II} = \frac{W_{II}}{\eta H_u} = \frac{347\,750}{4850} = 72 \text{ kg}.$$

Da sich mit jeder weiteren Betriebsstunde der Wärmeverlust durch die Absorption des Ofenmauerwerkes verringert, und zwar so weit, bis schließlich ein gewisser Beharrungszustand eingetreten ist, so kann man für weitere anschließende Betriebsstunden auf Grund von Erfahrungen und Messungen den Prozentsatz dieses Wärmeverlustes gleichmäßig herabsetzen bis zu der untersten Beharrungsgrenze von $\sim 15\%$.

Zahlentafel 1.

Anlage in	Koksart	Koksverbrauch in kg für Einäscherung: Hochheizen und 1.	2.	3.	4.	5.	6.	Bemerkungen
Arnstadt	Gas-	160–270	234–314 von zwei Leichen an einem Tage					Unregelmäßiger Betrieb. Abwärme für Kapellenheizung.
Berlin-Wilmersdorf	Gas-	350–52	52	52	50	50	50	Dauerbetrieb.
Chemnitz	Gas-	280	80	50	40	40	—	Dauerbetrieb. Heizversuche Heepke.
Dessau	Hütten-	265	180 zusammen				35	Heizversuche Keßler.
Erfurt	Gas-	182,5	87,5	112,5	110	50	25	Nicht täglich in Betrieb.
Halle	Hütten-	175–200	je 50					—
Hannover	Hütten-	etwa je 100 im Durchschnitt						Unregelmäßiger Betrieb.
Hirschberg	Hütten-	150	100	50	50	50	50	Saugzuganlage.
Mainz	Gas-	270	100	50	50	50	—	Modernisierter Ofen I — unterbrochener Betrieb
		400	200	100	100	—	—	Alter Ofen II — unterbrochener Betrieb
München	Gas-	200–210	52	52	52	52	—	—
Weimar	Gas-	je 135 im Durchschnitt						Nur Dienstags und Freitags in Betrieb.

Für anschließende dritte bis fünfte Einäscherung kommt man etwa mit dem Mittel zwischen 30 und 15%, also mit $\sim 22\%$ aus, so daß man erhält:

$$W_{III} = 0{,}22 (W_4 + W_5) + (W_1 + W_2 + W_3) - 0{,}85 \cdot (W_6 + W_7)$$
$$= 0{,}22 \cdot 1\,354\,000 - 98\,800 - 157\,250 = 239\,430 \text{ kcal}$$

und:

$$B_{III} = \frac{W_{III}}{\eta \cdot H_u} = \frac{239\,430}{4850} = 49{,}4 = \sim 50 \text{ kg}.$$

Von der fünften oder sechsten Einäscherung an wird der Beharrungszustand des Ofens in seiner Verlustwärmeabgabe annähernd erreicht sein, so daß man von jetzt an unbedenklich mit dem unteren Grenzwert von 15% rechnen darf. Somit gelten dann für eine weitere usw. Einäscherung:

$$W_n = 0{,}15 \cdot 1\,354\,000 + 98\,800 - 157\,250 = 144\,650 \text{ kcal}$$

und:

$$B_n = \frac{W_n}{\eta \cdot H_u} = \frac{144\,650}{4850} = 30 \text{ kg}.$$

Alle diese Rechnungsergebnisse decken sich gut mit praktischen Erfahrungen. In vielen Krematorien wird mit einem täglichen oder jährlichen Durchschnittswert je nach der Inanspruchnahme der Anstalten gerechnet. So findet man für eine erste Einäscherung einschließlich Anheizen:

$B = 175–275$ kg für einen normalen mittleren Ofen,
$= 300–450$ kg für einen schweren Ofen mit Dauerbetrieb,
$= 75–80$ kg für eine weitere anschließende Einäscherung.

Document 91: continued

Wegen der Verrechnungen des Brennstoffverbrauches über eine längere Betriebszeit hin seitens der Krematorienverwaltungen finden sich nur wenig feste Werte für den Koksverbrauch für die einzelnen aufeinanderfolgenden Einäscherungen. Diese Werte lassen sich dann nur durch Heizversuche gewinnen. In vorstehender Zahlentafel 1 ist eine diesbezügliche beschränkte Übersicht gegeben. Die Hochheizzeit ist mit ~2÷3 Stunden, die Einäscherungszeit mit $^3/_4$÷1$^1/_2$ Stunden vorauszusetzen. Von der Angabe der Ofensysteme ist absichtlich Abstand genommen.

Die größte Zahl der Einäscherungen im Koksofen hat sich im Jahre 1930 im Berlin-Wilmersdorfer Krematorium mit 3784 ergeben, also bei 52 Jahreswochen und 6 wöchentlichen Arbeitstagen im Durchschnitt täglich zu $\frac{3780}{52 \cdot 6} = \sim 12$; hierfür wurden 35 kg für jede Einäscherung verrechnet.

Für die zu erhebende Gebühr für eine Leichenäscherung kann natürlich nicht nur ein mittlerer Koksverbrauch herangezogen werden, sondern es müssen auch alle anderen Unkosten des Krematoriumsbetriebes prozentuale Berücksichtigung finden und dann aus der Jahresbilanz der Preis für eine Einäscherung festgelegt werden. Zieht man zum Beispiel Chemnitzer Verhältnisse herbei, so kommt man zu folgender Aufstellung:

Im Jahre 1930 sind im Chemnitzer Krematorium 1753 Leichen eingeäschert und dafür 128 t Koks verbraucht worden. Somit entfällt auf eine Einäscherung ein Koksverbrauch von 128000 : 1753 = 73 kg. Damit erhält man folgende Verrechnung:

73 kg Koks bei 100 kg zu 3 RM.	2,20 RM.
Anfuhr für 100 kg zu 0,38 RM.	0,27 „
Anzündeholz	0,13 „
Aschenabfuhr	0,10 „
6 Heizer-Lohnstunden je 1,20 RM.	7,20 „
(4 Heizer × 48 Wochenstunden × 52 Jahreswochen = 10000 Arbeitsstunden; 10000 : 1753 = 6 Heizerlohnstunden je Einäscherung)	
Von 7,20 RM. 25% für Versicherung usw.	1,80 „
	11,70 RM.
Davon 15% für Ofenabnutzung	1,75 „
Aschenkapsel	1,65 „
Harmoniumbenutzung	4,80 „
4 Trägerstunden je 1 RM.	4,— „
	23,10 RM.
Davon 30% für Verwaltungskosten	6,90 „
Somit Durchschnittsgebühr für eine Einäscherung	30,— RM.

[178]

Umschau.

Über das Mischen verschiedener Heizgase für die Städteversorgung. Das genaue Mischen verschiedener Gase zwecks Herstellung eines völlig konstanten Stadtgases ist heute von großer Bedeutung, und zwar namentlich für die amerikanischen Gaswerke, denen außer Steinkohlengas, Wassergas und Generatorgas auch noch Naturgas, ferner Abfallgase der Ölraffinerien, Butan, Propan usw. zur Verfügung stehen. Die Heranziehung dieser in ihrer Zusammensetzung so verschiedenen Gase für die Abgabe an Städte hat an die Meßtechnik bisher unbekannte Anforderungen gestellt. Früher hat man beim Mischen verschiedener Gase zur wenig auf die Einhaltung genauer Mengenverhältnisse geachtet, weil man sich über die Bedeutung einer konstanten Gasbeschaffenheit nicht im klaren war. Heute weiß man dagegen überall in der Gasindustrie, wie wichtig die Unveränderlichkeit des Heizwertes, des spezifischen Gewichtes und der anderen Brenneigenschaften des Stadtgases ist. In Amerika beträgt der Heizwert des Stadtgases in der Regel 4450—5030 kcal/m³, und zwar ist den Gasgesellschaften die Einhaltung eines bestimmten Heizwertes meist von einer staatlichen Kommission vorgeschrieben.

Die Gasgesellschaften haben zur Ausbildung oder zur Anschaffung zuverlässiger Meß- und Kontrollgeräte beträchtliche Mittel aufgewendet, so daß man heute überall selbsttätige Kalorimeter, Heizwertregler, Dichteschreiber und andere Kontrollgeräte benutzt. Die Consolidated Gas Electric Light & Power Co., die die Stadt Baltimore und deren Umgebung mit Gas versorgt, verteilt z. B. an ihre Abnehmer ein Gas, das aus Kokereigas, Ölraffineriegas und selbsterzeugtem karburierten Wassergas besteht. Die von auswärts bezogenen beiden Gase werden häufig in schwankenden Mengen und mit wechselndem Heizwert geliefert, trotzdem ist es dem Gaswerk gelungen, durch entsprechenden Zusatz von Wassergas, das mehr oder weniger stark karburiert wird, dauernd ein gleichmäßig zusammengesetztes Mischgas in das Rohrnetz zu speisen. Der Heizwert des abgegebenen Gases beträgt im Monatsdurchschnitt 4450 kcal/m³, wobei die Schwankungen für jede Einzelablesung im Mittel nur 90 kcal unter oder 180 kcal über diesem Wert liegen. Das spezifische Gewicht des Mischgases schwankt zwischen 0,55 und 0,63 (auf Luft = 1 bezogen).

Zur Erzielung dieser gleichmäßigen Gasbeschaffenheit werden im Gaswerk die 3 Einzelgase genauestens gemessen und mit Hilfe zahlreicher Kontrollgeräte auf ihren Heizwert und ihr spezifisches Gewicht untersucht, ebenso das Mischgas vor dem Eintritt in den Ausgleichbehälter sowie das Stadtgas vor dem Eintritt in das Rohrnetz. Im Originalaufsatz wiedergegebene Meßstreifen zeigen die Schwankungen im Heizwert und im spezifischen Gewicht der Einzelgase sowie die völlig gleichmäßige Beschaffenheit des Stadtgases. Zur Ausführung der Messungen werden registrierende Thomas-Kalorimeter sowie Reinarex-Dichteschreiber verwendet, deren Anzeigen durch häufige Vergleichsmessungen mit Standardinstrumenten von sorgfältig ausgebildeten Leuten systematisch kontrolliert werden.

Das Koksofengas wird von einem Stahlwerk in der Umgebung durch eine 13 Meilen lange Rohrleitung dem Gaswerk zugeführt. Die Gaslieferungen schwanken zwischen 17000 und 23000 m³/h, der Heizwert des Gases zwischen 4270 und 4720 kcal/m³ und das spezifische Gewicht zwischen 0,37 und 0,45. Das Koksofengas wird auf dem Gaswerk von Schwefelwasserstoff befreit und hierauf mit den anderen Gasen gemischt. Das Raffineriegas wird ebenso durch eine 5 Meilen lange Rohrleitung von einer benachbarten Ölraffinerie bezogen, und zwar in einer Menge von 2250—3400 m³/h; sein Heizwert beträgt 13350—13800 kcal/m³ und seine Dichte 0,95—1,0. Auch dieses Gas wird auf dem Gaswerk von Schwefelwasserstoff gereinigt, ehe es den anderen Gasen zugesetzt wird. Die eigene Wassergasanlage des Werkes muß imstande sein, den Tagesbedarf von durchschnittlich 850000 m³ im Sommer und von 1,3 Mill. m³ im Winter zum Teil, im Notfalle aber auch vollständig zu decken, und zwar muß dieses Gas durchaus den oben erwähnten Anforderungen entsprechen. Zu diesem Zweck sind 20 dreiteilige Wassergas-Einheiten, Bauart Lowe, vorhanden, die eine ausreichende Reserve bilden, selbst wenn die Lieferung von Kokerei- oder Raffineriegas ausbleiben sollte. Der Heizwert des Wassergases läßt sich durch Verändern der eingespritzten Ölmenge in weiten Grenzen regeln, desgleichen das spezifische Gewicht durch geeignete Einstellung der Perioden bei der Gaserzeugung. Die innige Vermischung der 3 Gase erfolgt in einem Feld-Waschet, in dem zugleich das Naphthalin aus dem Gase ausgewaschen wird, sowie in 4 großen Gasbehältern. (J. H. Wolfe, Ch. Met. Engg. 38, 1931, S. 578—581.) S. [213]

Feuerfeste Massen als Anstrich-, Reparatur- und Ausfugmaterial. Um höher beanspruchte feuerfeste Auskleidungen von Feuerungen und Öfen längere Zeit hindurch betriebsfähig zu halten, ist man in neuerer Zeit mehr und mehr zur Verwendung von Stampfmassen übergegangen, welche in verschiedensten Zusammensetzungen entsprechend der Art der Beanspruchung angeboten werden. Grundsätzlich unterscheidet man zwischen sogenannten Schutzüberzügen einerseits und den Flick- und Ausfugmassen andererseits. Während erstere — wie der Name schon sagt — zum Schutz des Mauerwerks als Überzug in verhältnismäßig dünner Schicht aufgetragen werden, nimmt man mit den Flickmassen meist Reparaturen an vorzeitig abgenutzten Stellen des Mauerwerks vor. Der Vorteil bei der Verwendung von Schutzanstrich- und Flickmassen liegt vornehmlich in ihrer billigeren Anwendung, da man bedeutend geringere Mengen dieses Materials im Vergleich zu einer Reparatur mit Steinmaterial benötigt, welches zwecks Erreichung einer genügenden Verbandsfestigkeit immer in größerem Umfange ersetzt werden muß. Man hat Massen entwickelt, welche in ihrer Feuerfestigkeit und chemischen Widerstandsfähigkeit dem Steinmaterial der Auskleidung erheblich überlegen sind, wobei die Gesamtkosten einer Reparatur trotz höherem absolutem Preis sich erheblich niedriger stellen. Eine für genannte Zwecke besonders geeignete Masse wird unter dem Handelsnamen „Pyro“[1]) auf den Markt gebracht. Als Schutzüberzug auf neuem Mauerwerk angewandt, bewirkt diese Masse eine wesentliche Verlängerung der Lebensdauer des Mauerwerks. Außer ihrer hohen Feuerbeständigkeit zeichnet sich Pyro-Masse auch durch eine große Widerstandsfähigkeit gegen chemischen Angriff von Schlacken und Flugstaub der Feuergase aus. Die Anwendung erfolgt in der Weise, daß man die pulverförmig in trockenem Zustand angelieferte Masse mit Wasser zu einem dünnflüssigen Brei anrührt, welchen man mit Hilfe einer Bürste auf das feuerfeste Mauerwerk aufträgt. Der Verbrauch dieser Masse ist sehr sparsam, da für einen Quadratmeter Mauerwerksfläche nur etwa 6 kg benötigt werden. Bei einem Preis von nur 0,27 RM. pro kg stehen die Kosten in sehr günstigem Verhältnis zur Verlängerung der Betriebsbeständigkeit des Mauerwerks. Wegen der chemischen Unempfindlichkeit der Pyro-Masse wird ein hiermit versehenes Mauerwerk von Schlackenkorrosionen bewahrt

Verordnung
zur Durchführung des Feuerbestattungsgesetzes *).
Vom 10. August 1938.

Auf Grund des § 10 des Gesetzes über die Feuerbestattung vom 15. Mai 1934 (Reichsgesetzbl. I S. 380) wird verordnet:

§ 1

Die vor Inkrafttreten des Gesetzes auf Formblatt eines Feuerbestattungsvereins abgegebene, eigenhändig unterschriebene Erklärung, durch die der auf Feuerbestattung gerichtete Wille bekundet ist, bleibt, auch wenn sie nicht eigenhändig geschrieben ist, wirksam.

§ 2

(1) Die Polizeibehörde des Einäscherungsortes hat über alle von ihr genehmigten Feuerbestattungen, gegebenenfalls für jede selbständige Anlage gesondert, ein Verzeichnis zu führen, in das unter fortlaufenden Nummern einzutragen sind:

1. Zu- und Vorname des Verstorbenen,
2. Geburtstag und Geburtsort,
3. Todestag und Sterbeort,
4. letzter Wohnort,
5. Stand oder Beruf,
6. Konfession,
7. Todesursache,
8. Tag und Stunde der Einäscherung,
9. Ausstellungstag und Nummer der Genehmigungsurkunde,
10. Beisetzungsort der Aschenreste,
11. Änderungen des Beisetzungsortes der Aschenreste (§ 10 Abs. 2).

(2) Das Verzeichnis ist mit den der Genehmigung zugrunde liegenden Bescheinigungen und Nachweisen 30 Jahre nach der letzten im Verzeichnis erfolgten Eintragung aufzubewahren.

§ 3

(1) Die nach § 3 Abs. 2 Nr. 2 des Gesetzes vorgeschriebene amtsärztliche Bescheinigung ist durch den für den Sterbeort oder für den Ort der Einäscherung zuständigen Amts- oder Gerichtsarzt nach anliegendem Muster auszustellen.

(2) Die obersten Landesbehörden können, soweit nötig, zur Vornahme der Leichenschau und zur Ausstellung der Bescheinigung auch andere Ärzte ermächtigen, die die amtsärztliche Prüfung als Kreis-, Bezirks- oder Gerichtsarzt bestanden oder an einem Sonderlehrgang mit Erfolg teilgenommen haben, durch den die für die gerichtliche Leichenschau erforderlichen Kenntnisse vermittelt werden, oder die bereits vor Inkrafttreten des Gesetzes mit Wahrnehmung dieser Verrichtungen betraut waren.

*) Betrifft nicht das Land Österreich.

§ 4

Bei Leichen, die aus dem Ausland zur Einäscherung eingeliefert werden, entscheidet die Polizeibehörde des Einäscherungsortes, ob der gemäß den Bestimmungen des Internationalen Abkommens über Leichenbeförderung ausgestellte Leichenpaß für den Nachweis der Todesursache ausreicht. Etwa bestehende Zweifel sind durch Vornahme der amtsärztlichen Leichenschau gemäß § 3 Abs. 2 Nr. 2 des Gesetzes zu klären.

§ 5

Die auf Feuerbestattung gerichtete Willensbekundung kann widerrufen werden. Der Widerruf muß einwandfrei nachgewiesen werden; als einwandfrei nachgewiesen gilt der Widerruf insbesondere dann, wenn er in einer der Formen des § 4 Nrn. 1 bis 3 des Gesetzes erklärt ist.

§ 6

Für die Feuerbestattungsanlage muß eine Leichenhalle vorhanden sein, in der die Leichen vor der Einäscherung untergebracht werden können. Außerdem muß ein Raum für die Vornahme der Leichenöffnungen zur Verfügung stehen, der die für diesen Zweck erforderlichen Einrichtungen zu enthalten hat.

§ 7

Die Feuerbestattungsanlage und deren Betrieb unterliegen der Aufsicht der Polizeibehörde des Ortes, in dem die Anlage sich befindet. Der Betrieb regelt sich nach einer von der obersten Landesbehörde zu genehmigenden Betriebsordnung, in der auch die Gebühren festzusetzen sind.

§ 8

Der für den Betrieb der Feuerbestattungsanlage verantwortliche Leiter ist von der die Aufsicht führenden Polizeibehörde ausdrücklich in Pflicht zu nehmen.

§ 9

Die Einäscherung darf erst erfolgen, wenn die schriftliche Genehmigung der Polizeibehörde des Einäscherungsortes (§ 3 des Gesetzes) dem für den Betrieb der Feuerbestattungsanlage verantwortlichen Leiter vorgelegt worden ist. Die Einäscherung ist innerhalb dreimal 24 Stunden nach erfolgter polizeilicher Genehmigung vorzunehmen. Kann die Frist nicht eingehalten werden, so hat der für den Betrieb der Feuerbestattungsanlage verantwortliche Leiter unter Angabe des Grundes der Verzögerung bei der Polizeibehörde eine Verlängerung der Frist zu beantragen.

§ 10

(1) Der für die Feuerbestattungsanlage verantwortliche Betriebsleiter hat die Einäscherung sowie die Beisetzung oder Versendung der Aschenreste unverzüglich der zuständigen Polizeibehörde mitzuteilen. Hierbei sind anzugeben: Zu- und Vorname des Eingeäscherten, Nummer und Ausstellungstag der polizeilichen Genehmigungsurkunde, Zeitpunkt der Ein-

Document 92a: "Ordinance for the Implementation of the Cremation Act" of 10 August 1938. Source: Reichsgesetzblatt*, Jahrgang 1938, Teil I, pp. 1000f.*

äscherung sowie Zeit und Ort der Beisetzung der Aschenreste, im Falle ihrer Versendung Anschrift, unter der die Aschenreste versandt worden sind. Der Versand von Aschenresten darf erst erfolgen, wenn dem Betriebsleiter eine Bescheinigung der Friedhofsverwaltung über die Genehmigung zu ihrer Beisetzung vorliegt.

(2) Sind die Aschenreste zwecks Beisetzung nach einem anderen Orte versandt worden, so hat die Friedhofsverwaltung oder die Polizeibehörde dieses Ortes der Polizeibehörde des Einäscherungsortes die erfolgte Beisetzung anzuzeigen. Auch eine Versendung bereits beigesetzter Aschenreste ist der Polizeibehörde des Einäscherungsortes mitzuteilen.

(3) Die Aushändigung der Aschenreste an die Angehörigen oder deren Beauftragte, auch zwecks Beisetzung an einem anderen Orte, ist vorbehaltlich der Ausnahme im § 9 Abs. 3 des Gesetzes nicht zulässig.

(4) Die Ruhefrist für die Aschenreste beträgt 20 Jahre, wenn für die Erdbestattung am gleichen Orte eine Ruhefrist von 20 Jahren oder mehr vorgesehen ist; in allen übrigen Fällen ist die Ruhefrist für Aschenreste mindestens auf den als Ruhefrist bei Erdbestattungen am gleichen Orte vorgesehenen Zeitraum zu bemessen. Nach Ablauf der Ruhefrist sind die alsdann noch vorhandenen und als solche erkennbaren Aschenreste und ihre Behältnisse in einer Gemeinschaftsgrabstelle dem Erdboden einzuverleiben.

§ 11

(1) Über die in der Feuerbestattungsanlage vorgenommenen Einäscherungen ist ein Verzeichnis nach beigefügtem Muster (Einäscherungsverzeichnis) zu führen. Das Verzeichnis ist am Ende jedes Kalenderjahrs abzuschließen und mit dem von der Polizeibehörde geführten Verzeichnis (§ 2) abzustimmen.

(2) Das Einäscherungsverzeichnis mit den ihm zugrunde liegenden Genehmigungsurkunden ist 30 Jahre nach der letzten im Verzeichnis erfolgten Eintragung aufzubewahren.

§ 12

(1) Die Leichen sind in den Särgen oder Einsatzsärgen einzuäschern, in denen sie zur Feuerbestattungsanlage gelangen. Die Särge müssen aus dünnem Holz oder Zinkblech bestehen und frei von Metallbeschlägen sein. Pech darf zur Abdichtung der Fugen nicht verwendet werden. Als Unterlage für die Leiche sowie als Füllmasse für etwaige Kissen sind Säge- oder Hobelspäne, Holzwolle oder Torfmull zu benutzen. Die Auskleidung des Sarges sowie die Bekleidung der Leiche kann in der üblichen Weise erfolgen, doch sind zur Befestigung der Auskleidung Metallstifte und zum Schließen der Kleidung Nadeln, Haken oder Ösen unzulässig, dagegen einfache umsponnene Knöpfe gestattet.

(2) Der Reichsminister des Innern kann zur Herstellung von Särgen sowie als Unterlage für die Leiche und als Füllmasse für die Kissen an Stelle der im Abs. 1 genannten Stoffe auch andere Stoffe zulassen.

§ 13

In jeder Einäscherungskammer darf jeweilig nur eine Leiche eingeäschert werden. An den Särgen ist vor der Einbringung in den Verbrennungsofen ein durch die Ofenhitze nicht zerstörbares Schild anzubringen, auf welchem die Nummer, unter der die Eintragung in das Einäscherungsverzeichnis erfolgt ist, sowie der Name der Feuerbestattungsanlage deutlich sichtbar eingeschlagen sein muß. Die Aschenreste jeder Leiche sind mit dem Nummernschild in einem widerstandsfähigen, dauerhaften, luft- und wasserdichten Behältnis zu sammeln, das durch eine amtlich bestellte Person zu verschließen ist. Der Deckel des Behältnisses ist mit einem festsitzenden, dauerhaften Schild zu versehen, das in deutlicher geprägter Schrift folgende Angaben zu enthalten hat:

1. die mit dem Einäscherungsverzeichnis und dem Nummernschild in der Asche übereinstimmende Einäscherungsnummer,
2. Zu- und Vorname sowie Stand des Verstorbenen,
3. Ort, Tag und Jahr seiner Geburt,
4. Ort, Tag und Jahr seines Todes,
5. Ort und Tag der Einäscherung.

§ 14

(1) Die durch die amtsärztliche Leichenschau entstehenden Kosten sind nach den Mindestsätzen der Gebührenordnung für amts- oder gerichtsärztliche Verrichtungen zu berechnen. Außerdem sind die notwendigen Reisekosten zu erstatten. Die entstehenden Kosten fallen dem Bestattungspflichtigen zur Last.

(2) Soweit für das polizeiliche Genehmigungsverfahren Gebühren erhoben werden, sollen sie den Betrag von drei Reichsmark nicht übersteigen.

§ 15

(1) Diese Verordnung tritt mit dem auf die Verkündung folgenden Tage in Kraft.

(2) Gleichzeitig treten außer Kraft:

die Verordnung zur Durchführung des Feuerbestattungsgesetzes vom 26. Juni 1934 (Reichsgesetzbl. I S. 519),

die Verordnung über die Änderung der Verordnung zur Durchführung des Feuerbestattungsgesetzes vom 16. Oktober 1936 (Reichsgesetzbl. I S. 884) und

die Zweite Verordnung über die Änderung der Verordnung zur Durchführung des Feuerbestattungsgesetzes vom 13. Oktober 1937 (Reichsgesetzbl. I S. 1132).

Berlin, den 10. August 1938.

Der Reichsminister des Innern
In Vertretung
Dr. Stuckart

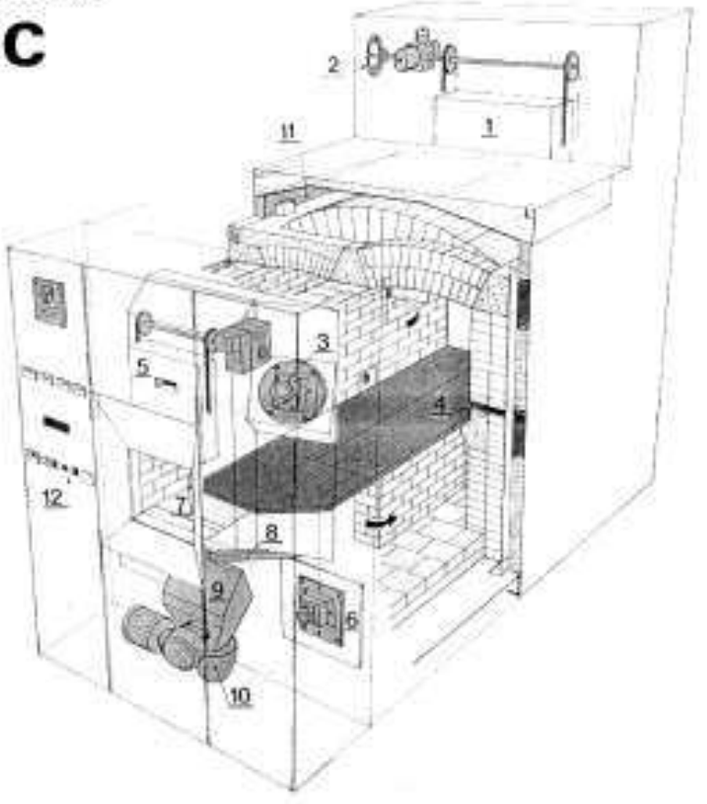
CONCEPTION MONOBLOC



① Porte d'introduction
② Commande manuelle de secours
③ Brûleur de préchauffage
④ Tuyères de soufflage
⑤ Porte de service
⑥ Brûleur de post-combustion
⑦ Foyer secondaire
⑧ Grille mobile
⑨ Broyeur incorporé
⑩ Urne
⑪ Circuit de réchauffage d'air
⑫ Tableau de commande

SES AVANTAGES :

- Le four est entièrement construit dans notre usine de Gaillon puis séché et testé sur plate-forme d'essais. L'ensemble des équipements et les séquences de fonctionnement et de sécurité sont ainsi complétement contrôlés et vérifiés avant livraison. Il ne reste plus à effectuer sur site que les branchements de combustible et d'électricité.

- Cette conception, permettant la livraison sur site d'un ensemble complet, améliore la qualité finale du matériel, réduit la durée des travaux sur site et les aléas de montage et de mise en route. De plus, elle limite considérablement les pertubations qu'un chantier de cette nature peut apporter sur l'exploitation d'un crématorium.

Four C 411 en cours de fabrication

LA CONCEPTION DU FOUR TABO

L'ossature métallique,
renforcée du four est réalisée à partir de profilés également utilisés pour la distribution de l'air primaire, secondaire et tertiaire.

La structure réfractaire et isolante,
du four est constituée de 3 parties essentielles :
- la chambre de crémation
- les chambres de mélange
- la chambre de post-combustion

De la chambre de crémation,
les gaz issus de l'autocombustion sont, selon un procédé exclusif, intimement mélangés à l'air secondaire dans la double paroi du four pour permettre un processus pyrolitique contrôlé par la sonde à oxygène, l'air tertiaire et le brûleur dans la chambre de post-combustion.

L'utilisation de réfractaires denses,
contenant de 42 % à 64 % d'alumine, de matériaux isolants modernes, et de l'échangeur de chaleur introduit par TABO, assurent une crémation parfaite dans des conditions économiques d'exploitation.

Les équipements électriques,
mécaniques et thermiques sont regroupés de façon rationnelle et facilement accessibles du côté service.

L'utilisation de brûleurs,
industriels permet de déplacer les ventilateurs dans un local approprié.

La conception,
du four TABO permet indifféremment son assemblage sur place ou en usine.

J. A. Topf & Soehne

Maschinenfabrik · Feuerungstechnisches Baugeschäft

Feuerungstechn. Laboratorium · Eigene Versuchsstation

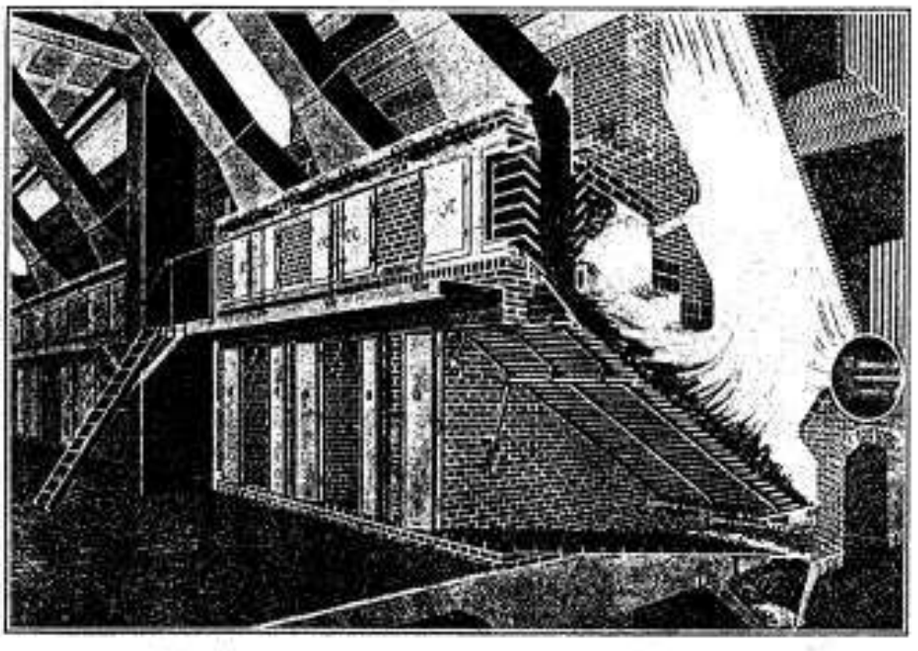
ERFURT

*

Die Firma wurde im Jahre 1878 durch Herrn J. A. Topf gegründet, der sich bereits vorher lange Zeit mit der Verbesserung industrieller Feuerungen eingehend befaßt hatte, nachdem er auf Grund seiner Tätigkeit als Brauerei-Fachmann zu der Ueberzeugung gelangte, daß das unwirtschaftliche Arbeiten der in dieser Zeit angewendeten Feuerungen eine Verbesserung der damals vorhandenen Einrichtungen erforderlich machte. In seinen Söhnen waren ihm tatkräftige Mitarbeiter erstanden, so daß das Gebiet der Feuerungstechnik durch Zusammenarbeit des Chemikers mit dem Techniker erfolgreich bearbeitet werden konnte.

In den beiden Hauptabteilungen für **Entwurf und Ausführung zeitgemäßer Dampfkessel-Anlagen** sowie die **Einrichtung kompletter Mälzereien** sind die darin behandelten Gebiete in einer Weise gepflegt worden, daß es der Firma gelungen ist, sich nicht nur in Europa, sondern auch in allen übrigen Erdteilen einen Namen zu verschaffen.

Das Arbeitsgebiet der Abteilung für Dampfkessel-Anlagen umfaßt den Entwurf und die Ausführung aller feuerungstechnischen Bestandteile, die auf die Nutzwirkung und Leistungsfähigkeit solcher Anlagen maßgebenden Einfluß ausüben. Es sind dies insbesondere:



Topf'sche Halbdrehrostfeuerung mit seitwärtigem Vorfeuergewölbe an einem Steilrohrkessel

Lfd. Nr.	Ort	Tag der Eröffnung	Anzahl der vorhandenen Oefen	Ofensystem und Baufirma
79	Eisfeld	29. 9. 27	1	J. A. Topf & Soehne, Erfurt
80	Ludwigsburg	22. 10. 27	1	Wilhelm Ruppmann, Stuttgart
81	Hildburghausen	27. 10. 27	1	J. A. Topf & Soehne, Erfurt
82	Freiberg i. S.	2. 3. 28	1	Gebr. Beck, Offenbach a. M.
83	Quedlinburg	10. 3. 28	1	J. A. Topf & Soehne, Erfurt

Durch nachträglichen Ofeneinbau wurden Friedhofskapellen in Krematorien umgewandelt in Jena, Offenbach, Eisenach, Reutlingen, Göppingen, Weimar, Sonneberg i. Th., Frankfurt a. M., München, Wiesbaden, Pforzheim, Konstanz, Ilmenau, Erfurt, Suhl, Magdeburg, Grünberg, Arnstadt i. Th., Bernburg, Stettin, Apolda, Wilhelmshaven, Liegnitz, Gießen, Weißenfels, Eisfeld, Ludwigsburg und Quedlinburg.

Als Heizmaterial verwenden die meisten deutschen Krematorien Koks, (Gas-, Kammerofen-, Zechen-, Schmelz-, Hütten-, Grob-, Destillations-Koks), Braunkohle und Koks vermischt findet in Gotha Verwendung. Koks und Holz werden verfeuert in Göppingen, Eßlingen, Freiburg i. Br. — Mit Gas werden Krematoriumsöfen beheizt in Dessau, Dresden, Ludwigsburg und Freiberg i. Sa.

Reine Baukosten des Gebäudes bzw. der durch den Ofeneinbau notwendigen Umbauten	Kosten der Ofenanlage	Einäscherungsziffer 1927	Einäscherungen seit Eröffnung	Gebühren für die Einäscherung nebst Ausschmückung und Beleuchtung der Trauerhalle sowie Orgelspiel	Lfd. Nr.
21 300,—	13 700,—	7	7	73,—	79
47 000,—	18 000,—	7	7	50,—	80
24 000,—	13 000,—	16	7	50,—	81
145 000,—	13 500,—	—	—	200,—	82
50 000,—	13 519,—	—	—	70,—	83
		45 752,—	389 138,—		

Die Zeitdauer der Einäscherung schwankt zwischen 45 Minuten bis zu 3 Stunden. An Koks werden verbraucht $1^1/_2$ bis $8^1/_2$ Zentner für die Einäscherung, an Gas 33 bis 260 cbm. Die gewaltigen Unterschiede der Zahlen sind dadurch zu erklären, daß seitens der Krematorien zwischen der Hochheizung des Ofens und der Nachheizung des noch warmen Ofens bei den Zahlenangaben nicht unterschieden worden ist.

Die Tabelle verdanken wir zum größten Teile dem Volksfeuerbestattungsverein V. V. a. G. in Berlin, der den Nachdruck gütigst gestattete. Für die Zwecke des Jahrbuchs wurde die Tabelle vereinfacht und zeitgemäß ergänzt, z. T. unter Benutzung der Statistik der „Deutsche Flamme".

Der

Feuerbestattungs-Ofen

SYSTEM RUPPMANN

beruht auf dem Prinzip, die Verbrennung in rein atmosphärischer und hocherhitzter Luft, praktisch rasch- und geruchlos vor sich gehen zu lassen, so dass dem ästhetischen Empfinden in vollstem Masse Rechnung getragen wird.

Ansicht des Krematoriums auf dem Prag-Friedhof in Stuttgart. — Erbauer Professor Schmitz in Stuttgart. — Der zweite Verbrennungsofen wurde von der Firma WILHELM RUPPMANN eingebaut.

Die in allen Teilen sorgfältig durchgearbeitete, auf 26jähriger feuerungstechnischer Erfahrung beruhende Konstruktion, die gewissenhaft solide Ausführung und die ausschliessliche Verwendung zweckentsprechenden Materials gewährleisten die guten Eigenschaften eines zeitgemässen Verbrennungsofens:

Vollkommene Verbrennung in rein glühender Luft ohne Einwirkung von Feuergasen aus der Feuerung!

Geräuschloser, reinlicher, durchaus sicherer und einwandfreier Betrieb! Einfache Bedienung! ☐ Kurze Verbrennungsdauer! ☐ Geringster Kohlenverbrauch!

Feuerbestattungs-Ofen

SYSTEM RUPPMANN

Der Ofen ist mit einer bedeutenden

Koks-Generator-Gasfeuerung

ausgestattet, welche auf neuzeitlicher Grundlage konstruiert und mit soliden, gut bearbeiteten Armaturen ausgestattet ist, die eine leichte, bequeme und sichere Bedienung in jeder Hinsicht ermöglichen.

Der Generatorschacht ist in seinen Dimensionen so bemessen, dass er diejenige Koksmenge fasst, welche notwendig ist, um den Verbrennungs- und Nachglühraum normalerweise, d. h. wenn der Ofen durchwärmt ist, innerhalb 3 Stunden von etwa 300° auf 950 bis 1000° Cels. hocherhitzen.

Der eigentliche

Verbrennungsraum

schliesst sich oben direkt an den Generator an. Er entspricht den vom Kongress für Feuerbestattungswesen festgelegten Dimensionen, ist 2500 mm lang, 950 mm breit und 950 mm hoch und bietet somit genügenden Raum für die grössten vorkommenden Särge von 2250 mm Länge, 750 mm Breite und 720 mm Höhe (Aussenmasse).

Ansicht der Stuttgarter Ofen-Anlage.
Der mit geöffneter Eintrittsvorrichtung dargestellte Ofen wurde Anfang 1929 erbaut von der Firma WILHELM RUPPMANN, STUTTGART.

Document 119: "The Cremation Furnace System Ruppmann." Advertising brochure published around 1918.

Der Sarg wird mit Handwagen oder mittelst mechanischer Einführungs-Vorrichtung eingefahren und automatisch auf einen Schamottenrost abgesetzt, worauf der Wagen sofort wieder zurückgeführt wird.

Zum Verschluss des Verbrennungsraumes dient ein zuverlässiger, in Eisen armierter, vollständig gedeckt abschliessender Schamotte-Schieber. Ausserdem wird als Abschluss nach aussen noch ein schwerer Winkelrahmen mit zweiflügeliger Türe in Kunstschmiedearbeit angebracht.

Unter dem Verbrennungsraum ist ein

Nachglühraum

angeordnet, auf dessen Herd die durch den Schamotterost fallenden Aschenteile des menschlichen Körpers ausglühen.

Vom Nachglühraum aus gelangen die Feuergase in eine wärmeausgleichend wirkende Rückhalzkammer, durch welche der Herd des ersteren auch von unten gründlich beheizt wird, worauf die Abgase in den Rekuperator eintreten.

Einer der wichtigsten Ofenteile ist der

a) Verbrennungsraum d) Rekuperator g) Kohlenschieber i) Saugzugleitung
b) Nachglühraum e) Einäscherungsraum h) Aschenfall k) Kaminschieber
c) Rückhalzkammer f) Gas-Generator i) Schamottsteinschieber m) Luftschieber

Rekuperator

System Ruppmann

welcher durch eine grössere Zahl enger Luftkanäle und weiter Feuerkanäle neben- und übereinander gebildet wird. Derselbe dient dazu, die Abhitze des Ofens, soweit praktisch irgend möglich, zur Vorwärmung der Verbrennungsluft auszunützen.

Bei dem im Gegenstromprinzip arbeitenden Ruppmannschen Rekuperator wird die Luft in enge Berührung mit den glühenden Schamotte-Wänden gebracht, wodurch allein die Gewähr für hohe Erhitzung grösserer Luftmengen geboten ist.

Um auch die nach aussen dringende Strahlwärme des oberen Verbrennungsraumes für die Verbrennungsluft zu gewinnen wird letztere zu beiden Seiten des Verbrennungsraumes hin- und hergeleitet und dann als hochtemperierte Luft in den Gasbrenner, gleichmässig verteilt, eingeführt.

Der gesamte Ofen ist äusserst kräftig konstruiert und wird durch nur eigenes, gutgeschultes Baupersonal unter Verwendung erstklassiger Materialien sorgfältig aufgebaut und solid verankert.

Zur genauen Einregulierung des Ofenbetriebs sind verschiedene Schieber in bewährter Anordnung eingebaut.

Allgemeines.

Die Verbrennung spielt sich in der Weise ab, dass nach Einführung des Sarges der Körper infolge Einwirkung der Strahlwärme ausgelöst und in Gasform überführt wird. Die dabei erzeugten Gase werden in glühendem Luftstrom vollständig zur Verbrennung gebracht.

Da bei Beginn des Einäscherungsprozesses die Koksfüllung im Generator (2 Stunden vor einer Kremation wird kein Brennstoff mehr nachgefüllt) bis auf einen kleinen glühenden Rest verzehrt ist, werden keine Gase und Flammen im Generator mehr entwickelt. Der Körper kommt demzufolge mit irgendwelchen Feuergasen überhaupt nicht in Berührung, wird vielmehr in rein glühender Luft verzehrt, welche in reichlicher Menge von meinem Rekuperator geliefert wird.

Mein Ofensystem bietet dadurch die sicherste Gewähr für eine vollständig einwandfreie Feuerbestattung in denkbar ästhetischster Form.

Die sich im Nachglühraum sammelnden Ueberreste verglühen auf dessen Herd zu rein weisser Asche, welche nach Verlauf von 2 Stunden dem Ofen entnommen werden kann. Die Dauer der Verbrennung beträgt normal 1¼—1¾ Stunden.

Ansicht des Verbrennungsofen im Krematorium Saarbrücken a. d. Ehrmann von der Firma WILHELM RUPPMANN, STUTTGART

Ausgeführte Anlagen:

AUGSBURG, BERN, BIEL, ESSLINGEN, GÖPPINGEN, KÖNIGSBERG, LUGANO PFORZHEIM, NÜRNBERG (2 Oefen), REUTLINGEN, STUTTGART, WINTERTHUR.

Ingenieurbesuch und Projekt-Ausarbeitung bereitwillig und kostenlos.

Gegebenenfalls wird die vollständige Ofenanlage in bereits vorliegende Baupläne eingezeichnet.

Eigenes Qualitäts-Schamottewerk. ▪▪▪ Eigenes, geschultes Baupersonal.

Eigene Armaturen-Werkstätten.

Feuerbestattungsöfen
System Ruppmann

Neueste
patentierte Konstruktion
für Leuchtgas, Öl oder Koks

Das neue patentierte Einäscherungsverfahren nach „System Ruppmann" zeichnet sich aus durch geringsten Brennstoffverbrauch, Verkürzung der Einäscherungszeit und rauch- u. geruchlosen Betrieb.

Feuerbestattungsöfen System Ruppmann
sind in nachgenannten Krematorien in Betrieb:
Augsburg, Bern, Biel, Bremerhaven, Chur, Eßlingen, Goppingen, Kiel, Königsberg, Lugano, Ludwigsburg, Nürnberg, Pforzheim, Reutlingen, Stuttgart, Winterthur.

Anfragen erbeten an:
Wilhelm Ruppmann - - Stuttgart
Postfach 54

Für
Kremationsanlagen
System Ruppmann
liefere ich
sämtliche
maschinelle Zubehöre:

Sargeinführungs-Wagen mit Handbetrieb
Automatische Sargeinführung mit elektrischem Antrieb
Sargversenkungseinrichtungen, elektrisch oder hydraulisch angetrieben
Komplette Saugzuganlagen (geräuschloser Betrieb)
Entlüftungsanlagen
Anlagen zur Ausnützung der Abwärme
Sämtliche Kontroll- und Meßapparate
Komplette Entwürfe und Dispositionsanlagen für Krematorien

Anfragen richten an:
Wilhelm Ruppmann - - Stuttgart
Postfach 54

Die Urne

Zeitschrift zur Förderung der Feuerbestattung
Monatliches Insertions-Organ

Verantwortlicher Schriftleiter: Hermann Findeisen, Meißen
Für den Anzeigenteil: Bruno Thieme, Meißen, Fernruf 2884

Zuschriften für den textlichen Teil sind an Herm. Findeisen, Meißen, Meixerstraße 3, zu richten.

Nachrichtenblatt des Feuerbestattungsvereins Meißen und Umgebung

mit seinen Ortsgruppen Weinböhla, Coswig, Lommatzsch, Nossen, Riesa und deren Umgebung. Eingetragener Verein

Geschäftsstelle: Paul Schröder, Meißen, Neugasse Nr. 1511
Fernsprecher Amt Meißen Nr. 3117

Redaktionelle Einsendungen und Inserate bis spätestens 20. jeden Monats erbeten. Inseratenpreis: 1 Feld (65 : 35 mm) 5 RM.

Der Verein ist politisch und kirchlich neutral

Nr. 3 | Meißen, März 1931 | 4. Jahrgang

Ein neues Einäscherungsverfahren.

Da wir unsere Leser von dem neuen Einäscherungsverfahren bereits unterrichtet haben, müssen wir zwecks Klärung der Frage auch die Gegenseite zu Worte kommen lassen, ohne zur Sache selbst Stellung zu nehmen. Dies ist zunächst noch eine Angelegenheit der Fachleute. Die Schriftleitung.

Im „Zentralblatt für Feuerbestattung" Jahrgang 1930 No. 5 erschien ein Aufsatz des Herrn Oberbaurat Dipl.-Ing. Volkmann Hamburg, über „Ein neues Einäscherungsverfahren," auf den im Interesse der Feuerbestattungs-Sache näher eingegangen werden muß.

Zunächst, wer ist der Verfasser, der den Nichteingeweihten als der ideale neutrale Verfechter einer neuzeitlichen Entwicklung der Feuerbestattungs-Öfen erscheinen muß, wenn ihm die inneren Zusammenhänge nicht bekannt sind. Herr Oberbaurat Dipl.-Ing Volkmann ist dienstlich Dezernent für die Feuerbestattung in Hamburg und mit Herrn Dipl.-Ing. Ludwig Unternehmer eines Patentes über ein Einäscherungsverfahren. Beide versuchen das Patent zu verwerten und zwar gegen eine Vergütung, wie sie auf diesem Gebiete nicht üblich war (pro Jahr wurde eine Mindestlizenz von 30000 *RM* verlangt). —

Der Titel des Artikels ist irreführend, denn „Ein neues Einäscherungsverfahren" steht nicht zur Debatte, wenn der Verfasser nicht wesentliche Punkte verschweigt. Daß man die Einäscherung mit möglichst geringem Luftüberschuß ausführt, ist allgemein bekannt und ergibt sich schon aus dem Bestreben, den Gasverbrauch niedrig zu halten und mit geringem Zug auszukommen. Die Idee ist also durchaus nicht neu und wenn man bisher auf Methoden, wie sie in Hamburg angewendet werden, verzichtet hat, so geschah dies wohl aus dem Bestreben heraus, die Feuerbestattung nicht auf die Stufe der Cadaververnichtung sinken zu lassen, sondern hierbei nicht allein den Brennstoff-Verbrauch, sondern vor allem Gründe der Hygiene und der Pietät zu berücksichtigen. Daß letzteres in Hamburg nicht ausreichend geschieht, ergibt sich schon daraus, daß während des Einäscherungsvorganges ein Gasrohr bis an die schwer verbrennbaren Körperteile herangeschoben und letztere mit Druckluft angeblasen werden. Ein weiterer Kommentar hierzu ist wohl überflüssig.

Der Verfasser nimmt das Verdienst für sich in Anspruch, daß seine Untersuchungen den Nachweis erbracht hätten, von der Vergleichbarkeit der wirtschaftlichen Grundsätze für Einäscherungs- und andere Öfen. Wenn der Verfasser diese Übertragbarkeit der für die Wirtschaftlichkeit maßgebenden Grundsätze tatsächlich herausgefunden hätte, so wäre das keine überwältigende Entdeckung. Man muß aber sehr vorsichtig sein, wenn man Krematoriumsbetriebe mit industriellen Feuerungen oder mit Kadaver-Vernichtungsöfen vom Standpunkte der Wirtschaftlichkeit in Vergleich setzt. Der Vergleich wird aber ganz bedenklich im punkto Luftüberschuß, also vom rein technischen Gesichtspunkte, denn man kann selbstverständlich die Einäscherung einer Leiche mit dem Betriebe eines Industrieofens nicht vergleichen, weil die Materie zu große Verschiedenheiten aufweist.

Auf Seite 66 Absatz 1 weist der Verfasser darauf hin, daß in den Öfen der bekannten Systeme die Verteilung der Verbrennungsluft insofern mangelhaft wäre, als öfters gerade dort Luftmangel herrsche, wo Sauerstoff dringend benötigt würde und an anderen Stellen zum Schaden der Wärme-Ökonomie ein Überschuß daran festzustellen sei. Das führt der Verfasser auf eine bei den Industrie-Öfen bezw. Feuerungen beobachtete Erscheinung nämlich die mangelhafte Durchmischung der Feuergase mit der Verbrennungsluft zurück. Die Darstellung der laminaren Strömungen - paralleles nebeneinanderfließen von Feuergasen und Verbrennungsluft - ist praktisch ganz abwegig. In einem Einäscherungsofen treten durch die vielen Umlenkungen der Strömungsrichtung ganz überwiegend turbulente Strömungen auf, die ein genügendes Durcheinandermischen der Gase zur Folge haben.

Im Absatz 2 geht der Verfasser näher auf den Verbrennungsvorgang selbst ein. Er behauptet, nach Zerfallen des Sarges verschlechtere sich die Luftzufuhr zur Leiche und damit deren Verbrennung, deshalb, weil von da ab der in der Muffel für die Luft verfügbare Raum ungleich größer geworden sei und mit fortschreitender Einäscherung weiter wachse. Dieser Satz zeugt von ganz verschwommenen feuerungstechnischen Kenntnissen. Es müßte eine Explosion, also eine blitzschnelle Verbrennung stattfinden, wenn man nicht im Stande sein sollte, das Luftquantum, welches dem Sargvolumen entspricht, genügend schnell zu ersetzen. Außerdem hat ja der Sarg von vornherein auch Luftinhalt.

Am meisten anfechtbar ist der folgende Satz:

„Da aber von der durch die Muffel streichenden Luft nur ein verschwindend kleiner Teil mit der Leiche selbst in Berührung kommen kann, so muß die chemische Verbindung des Auflösungsprozesses notwendigerweise unvollkommen verlaufen und wir erhalten das Bild des rauchenden Schornsteins."

Dies würde genau zutreffen, wenn man die Leiche auf eine massive Platte legt und Kühlluft (ohne Rekuperation) oben darüber streichen läßt. Dann ergibt sich naturgemäß ein Schwelen und kein Verbrennen. Das dürften also die Erfahrungen sein, die man mit einem rostlosen Ofen ohne Rekuperation machen müßte.

Document 129: "A Novel Cremation Procedure". Article by Kurt Prüfer. Source: Die Urne*, 4. Jg., Nr. 3, March 1931, pp. 27-29.*

Etwas ganz anderes ist es, wenn die Leiche in jedem Stadium der Einäscherung allseitig von Feuergasen umspült wird, weil sie auf einem Rost liegt, und wenn man dafür sorgt, daß diese Feuergase einen Überschuß von Luft haben, der zur restlosen Verbrennung der aus der Leiche selbst entwickelten Kohlen-Wasserstoffe ausreicht. Warum soll man das der Muffel zurückführende Luftquantum nicht genau regulieren können?

Es wird behauptet, daß in Hamburg 3500 Einäscherungen vorgenommen worden sind mit einem Gasverbrauch von insgesamt nur 100 cbm Gas. Dies muß zunächst bestritten werden, denn nach den Aussagen, die mir in Hamburg persönlich durch 2 den Ofen bedienende Heizer völlig unabhängig von einander gegeben worden sind, werden im allgemeinen ca 7 cbm Gas zugesetzt, vielleicht auch etwas mehr.

Um diese Frage zu prüfen, muß man sich etwas eingehender mit dem Problem befassen, ob eine menschliche Leiche so viel brennbare Bestandteile enthält, daß bei kontinuierlichem Betriebe des Ofens nach dem Anheizen und Erreichung des Beharrungszustandes keine Wärmezufuhr von außen notwendig ist. Nach mehreren medizinischen Autoren enthält der menschliche Körper durchschnittlich:

Wasser	65%	d. h. bei 70 kg	Körpergewicht	45	kg
Fett	12%	"	"	"	8,4	kg
Eiweißstoffe	15%	"	"	"	10,6	kg
and. chem. Stoffe	3,5%	"	"	"	4,5	kg
Asche	4,5%	"	"	"	3,2	kg
Sa.	100%			Sa.	60,7	kg

Es läßt sich danach leicht errechnen, daß allein der Fettgehalt mit einem Heizwert von 7500 WE ausreichen müßte, um das Wasser zu verdampfen und die übrigen Teile auf Entflammungstemperatur zu erwärmen, wenn keine Ausstrahlung nach außen in Frage kommt. Es kann also in Krematorien, bei denen die Einäscherungen laufend hintereinander erfolgen und bei guter Isolierung der Ofenwände zur Herabminderung der Wärmeverluste mit nur ganz geringem Gaszusatz gerechnet werden.

Das ist aber durchaus nichts neues, denn diese Erfahrung ist schon lange in Krematorien mit kontinuierlichem Betriebe gemacht worden.

Wenn die Behauptung der Einäscherung ohne jeden Gaszusatz zutreffen sollte, so müßte die Abgastemperatur — Raumtemperatur sein, was wohl ernstlich ein Feuerungstechniker nicht behaupten wird, denn die unvermeidlichn Abgasverluste und die beim Einführen des Sarges einströmende kalte Luft sind gewisse Passivposten in der Wärmebilanz, die sich nicht umgehen lassen.

Ich hatte übrigens Gelegenheit, den Hamburger Ofen nach eingeholter Genehmigung zu besichtigen und mehreren Einäscherungen beizuwohnen und knüpfe hieran noch folgende Bemerkungen.

Im Einäscherungsraume befindet sich ein kleiner Ofen, der nach erhaltener Erklärung den Versuchsofen darstellt, ferner ein in Bau befindlicher Ofen, der bis zur halben Muffelhöhe fertiggestellt ist. Der neu im Bau befindliche Ofen weicht in seiner Konstruktion erheblich von dem ersten ab, ist also ebenfalls wieder ein Versuchsofen, weil damit meines Erachtens Betriebserfahrungen noch nicht vorliegen.

Im Großen und Ganzen bietet der Hamburger Ofen, abgesehen von dem Wegfall der Rekuperation nicht viel neues, sondern er ist in seinen Einzelheiten vielfach von Konkurrenzöfen entlehnt. Weshalb sind die Herren Volkmann und Ludwig bei dem im Bau befindlichen Ofen von der in ihrer Patentschrift gekennzeichneten Bauart bereits wieder abgekommen, denn davon ist nicht mehr viel übrig geblieben? Doch wohl nur deshalb, weil der Versuch nicht restlos geglückt ist, wie man erwartet hat! Der erste Ofen ist mit einem engen Rost versehen, während bei dem zweiten noch nicht fertigen Ofen statt des Rostes eine Schamottepflatte vorgesehen ist, welch letztere nahezu das einzige ist, was von der patentierten Einrichtung noch beibehalten ist.

Der neueste Ofen hat am Kopfende 4 Stück Hochdruckbrenner, wie dies andere Systeme schon lange vorgesehen und an der Seite 2 senkrecht zur Muffel stehende Brenner (sogenannte Sperrbrenner); letztere sind in der Schweiz bereits seit 1918 angeordnet (siehe Patentschrift von Ludwig Heller, Rüti, Patentnummer 81 680). Diese Einrichtung ist also alles andere als neu!

Auffallend ist, daß bei dem letzten Ofen die Einführung der Luft von oben nach unten angewendet ist, eine Anordnung, die der Verfasser in Spalte 4 seines Artikels als mißglückten Versuch einer anderen Firma verurteilt.

Diese vorerst verurteilte neuerdings aber angewendete Anordnung „vom Muffelgewölbe etwas geneigt, sonst senkrecht zur Leiche Luft zuzuführen" ist von der Firma J. A. Topf & Söhne, Erfurt, bereits bei zahlreichen Öfen angewendet, ebenso der für den Hamburger Ofen angewendete Nachverbrennungsrost.

Wenn in Hamburg angestrebt worden ist, eine rauchfreie Verbrennung zu erreichen, so muß dieser Versuch als gescheitert angesehen werden, denn es konnte bei der Besichtigung ein zeitweise sehr starke Rauchentwicklung beobachtet werden, wie sie bei den bisher bewährten Topf'schen Ofen nicht auftreten.

Die Einäscherung einer Leiche nimmt in Hamburg durchschnittlich 80 — 90 Minuten in Anspruch, sodaß auch in dieser Hinsicht ein Fortschritt nicht zu verzeichnen ist.

Alles in Allem muß ich sagen, daß der Hamburger Ofen den Erwartungen, die ich nach den sensationellen Veröffentlichungen gestellt hatte, nicht entspricht.

K.P.

TOPF

Der Feuerbestattungsofen System „Topf" ist das Ergebnis nahezu fünfzigjähriger Erfahrungen auf feuerungstechnischem Gebiet und ist sowohl für direkte als auch indirekte Einäscherung geeignet. Der Ofen besteht aus dem Koksgenerator mit Umleitung der Kohlenoxydgase, dem für sich abgeschlossenen Einäscherungsraum (Muffel) und dem darunter angeordneten Kanalsystem (Rekuperator), welches für die Vorwärmung der für die Einäscherung erforderlichen Luft dient (siehe Abb. 2). Diese vorgewärmte Luft kommt mit den Rauchgasen nicht in Berührung, denn die Luftkanäle sind von den Rauchkanälen vollkommen getrennt, sodaß also die Einäscherung bei indirektem Betrieb tatsächlich mit reiner atmosphärischer Luft, welche nur auf dem Wege zur Muffel hochgradig erhitzt wird, erfolgt.

Abbildung 1. **Krematorium Erfurt, Einsegnungshalle**
Ausfahren des Sarges in Höhe des Einführfußbodens (ohne Versenkung)

Zwischen dem inneren und äußeren Ziegelmauerwerk wird über die ganze Länge und Höhe des Ofens eine starke Isolierschicht aus Kieselgursteinen angeordnet, durch welche die Wärmeausstrahlung auf ein Mindestmaß beschränkt wird. Bei der Durchbildung unserer neuesten Konstruktion haben wir gerade in dieser Hinsicht unsere wärmewirtschaftlichen Erfahrungen entsprechend verwertet. Die sich hieraus ergebenden Vorteile kommen hauptsächlich dann zur Geltung, wenn ein Ofen nicht täglich benutzt wird. Die Kieselgur-Isolierschicht hält den Ofen noch lange Zeit warm und bei Wiederinbetriebsetzung wird entsprechend weniger Heizmaterial benötigt. Außerdem verkürzt sich auch die Hochheizungsdauer ganz bedeutend.

Das Außenmauerwerk des Ofens wird nach dem bewährten Topfschen Bogensystem ausgeführt und zwar in der Weise, daß das Mauerwerk in Form stehender Gewölbe zwischen kräftigen Winkel- und I-Eisen-Trägern eingespannt wird. Diese Bauart gewährleistet eine sehr lange Lebensdauer und vermeidet Rissebildungen, die sonst infolge der hohen Temperaturen leicht auftreten würden. Die Armaturen werden aus feuerbeständigem Guß hergestellt.

Document 134: continued.

In den letzten Jahren haben wir für eine ganze Reihe kleinerer Städte Feuerbestattungsanlagen im Anschluß an bereits vorhandene Einsegnungshallen oder dergl. errichtet. Diese Anordnung, bei der in den meisten Fällen auch keine Versenkungsvorrichtung notwendig ist, gibt allen den Städten, die die Errichtung eines besonderen Krematoriums aus finanziellen Gründen immer wieder zurückstellen mußten, nunmehr die Möglichkeit, sich eine Einäscherungsanlage mit verhältnismäßig geringen Mitteln zu schaffen. Nach diesem Prinzip sind die Krematorien in

Erfurt (siehe Abb. 1)
Grünberg
Guben
Höchst a. M.
Ilmenau
Magdeburg
Suhl (siehe Abb. 3—5)

gebaut worden.

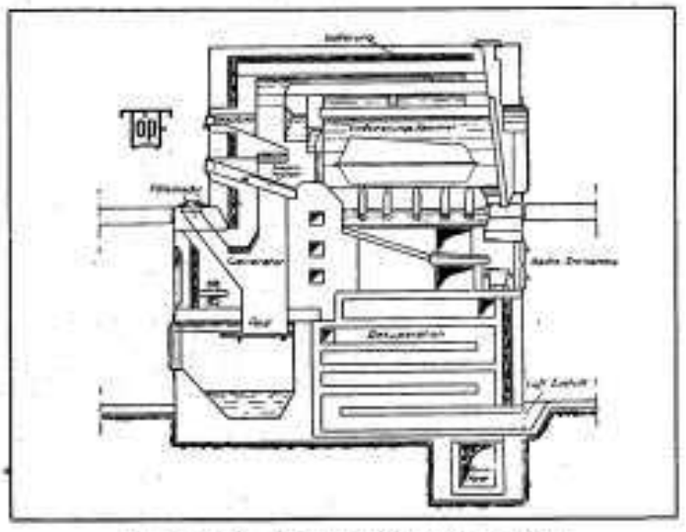

Abbildung 2. **Längsschnitt durch den Ofen**

Neuerdings ordnen wir zur Ausnutzung der Abgase Lufterhitzer an; das sind Apparate, die in den Fuchs kurz vor dem Schornstein eingebaut werden. Sie bestehen aus einem Wärmeaustauschkörper mit einer großen Anzahl sogenannter Taschen, in denen Rauchgase und Luft separat zirkulieren, ein davor geschalteter Ventilator saugt Frischluft an und drückt dieselbe durch die Lufttaschen. Durch die danebenliegenden Taschen werden die Rauchgase geleitet, die Luft wird auf diese Weise erwärmt und kann in Rohrleitungen nach der Einsegnungshalle geführt werden und dient gleichzeitig zur Heizung der Letzteren. Hierdurch wird eine besondere Zentralheizungsanlage überflüssig. Abgesehen davon, daß sich die Anschaffungskosten viel niedriger als diejenigen eines besonderen Heizkessels stellen, entstehen durch den kleinen Ventilator so verschwindend geringe Betriebskosten, daß die Heizung fast kostenlos möglich ist.

Document 134: continued.

Der Stadtdirektor
Arnstadt i. Th.
Abteilung IV.

Arnstadt, den 10. Februar 1925.

Firma J. A. Topf & Soehne, Erfurt.

Am 1. Oktober 1924 ist der von der Firma J. A. Topf & Soehne in Erfurt ausgeführte Einäscherungsofen übergeben und in Betrieb genommen worden. Bis heute haben 57 Einäscherungen stattgefunden. Die Einäscherungen finden unregelmäßig statt, deshalb ist die Hochheizungsdauer und der Koksverbrauch für die einzelnen Verbrennungen nicht gleichmäßig. Als Heizmaterial findet Gaskoks Verwendung. Die Hochheizung des Ofens erfolgt in 2—2½ Stunden.

Vom Anheizen bis zur Hochglut und restlosen Verbrennung ist folgender Koksverbrauch festgestellt worden:

Bei Einäscherung eines Leichnams 169—260 kg } einschl. Hochheizung
" " von 2 Leichen an einem Tage 234—314 kg }

Die Einäscherungen erfolgen rauch- und geruchlos in einem Zeitraum von ½ bis 1½ Stunde für jede Leiche. Der 18,0 m hohe, von der Firma J. A. Topf & Soehne erbaute Schornstein gibt zu Einwendungen keinerlei Veranlassung. Dasselbe gilt von der Verschlackungsvorrichtung, die gleichfalls von der Firma hergestellt ist.

In Verbindung mit dem Kanal für die Abführung der Gase vom Einäscherungsofen nach dem Schornstein ist von der Fa. J. A. Topf & Soehne eine Lufterhitzeranlage für die Beheizung der Friedhofskapelle eingebaut worden. Die Lufttemperatur an den Austrittsöffnungen in der Kapelle beträgt durchschnittlich 50° C. Bei Einäscherungen ist die Kapelle ohne jeden Aufwand für Brennstoffe in kurzer Zeit erwärmt.

Das Friedhofsamt.
gez.: Unterschrift.

Garten- und Friedhofsamt
der Stadt Erfurt.

Erfurt, 25. Juni 1925.

Firma J. A. Topf & Soehne, Erfurt.

Am 11. April 1923 wurde die von der Firma J. A. Topf & Soehne ausgeführte Einäscherungsanlage mit zwei Öfen in Betrieb genommen. In dieser Zeit bis zum heutigen Tage sind im ganzen 700 Einäscherungen erfolgt.

Nach zweijähriger Benutzung der Öfen sind Betriebsstörungen bislang nicht aufgetreten.

Infolge der besonderen Bauart der Öfen und ihrer guten Isolierung sind sehr geringe Temperaturschwankungen zu verzeichnen, was auf die Haltbarkeit des Mauerwerkes von großem Einfluß ist. Schäden irgendwelcher Art sind bis jetzt nicht festgestellt worden. Die außerordentlich einfache Bedienung der Öfen verdient hervorgehoben zu werden.

Leider sind die Verbrennungsöfen noch nicht täglich in Benutzung. Infolgedessen ist die Menge an Verbrennungsmaterialien für eine Leiche noch nicht gänzlich feststehend.

Nach den gemachten Aufzeichnungen ist bislang unter Verwendung von Gaskoks, gerechnet vom Anheizen bis zur Hochglut, restlose Verbrennung und Herausnahme der Aschereste, unter Berücksichtigung daß die Öfen nicht täglich geheizt werden, als Verbrauch festgestellt:

1.	Bei Einäscherungen von	1	Leiche	an einem Tage		3¼	Ztr.	Gaskoks
2.	"	"	2	Leichen	hintereinander	5	"	"
3.	"	"	3	"	"	7¼	"	"
4.	"	"	4	"	"	9	"	"
5.	"	"	5	"	"	10¼	"	"
6.	"	"	6	"	"	10½	"	"
7.	"	"	7	"	"	10½	"	"

Die Einrichtung des Topfschen Systems gestattet es, daß die Einäscherungen vollständig rauch- und geruchlos erfolgen.

Die Höchstdauer einer Einäscherung beträgt 1½ Stunde.

Das städtische Garten- u. Friedhofsamt

Der Stadtdirektor
der Landeshauptstadt (Bauamt)

Weimar, 30. Mai 1925.

Firma J. A. Topf & Soehne, Erfurt.

Auf Ihr Ansuchen vom 22. d. Mts. teilen wir Ihnen mit, daß der von Ihnen im hiesigen Krematorium erbaute Einäscherungsofen sich bis jetzt gut bewährt. Die Einäscherungen finden, um den Betrieb wirtschaftlicher zu gestalten, nur Dienstags und Freitags statt. Die Hochheizungsdauer beträgt 2—3 Stunden, die Zeit einer Einäscherung 1—1½ Stunde. Zu den letzten 24 Einäscherungen wurden im Durchschnitt je 2,7 hl Gaskoks verbraucht (einschl. Hochheizung).

Beigeordneter.
gez.: Unterschrift.

Verwaltung des
Gertrauden-Friedhofes.

Halle a. d. S., 7. Oktober 1924.

Firma J. A. Topf & Soehne, Erfurt.

Auf Ihr Schreiben vom 3. ds. Mts. bestätigen wir Ihnen gern, daß die im Jahre 1915 von Ihnen erbauten Einäscherungsöfen bisher zu unserer vollsten Zufriedenheit gearbeitet haben. Die Anlage ist am 15. 12. 1915 in Betrieb genommen und sind bis heute in beiden Öfen zusammen 2670 Leichen eingeäschert. Zur Erzielung einer Temperatur von 1000—1100 Grad Cels. benötigen wir beim vorher kalten Ofen ca. 3½ bis 4 Ztr. Hüttenkoks, während zum Hochheizen des im Betrieb befindlichen Ofens nur 1 Ztr. des gleichen Brennstoffes benötigt werden. Die Zeitdauer der Einäscherung richtet sich nach der Körpergröße des Verstorbenen und Beschaffenheit des Sarges, sie beträgt hier ¾ bis 1¼ Stunde.

gez.: Unterschrift.

Städtische Betriebswerke.
Heizungs- u. Maschinenwesen.

Hannover, 10. Oktober 1924.

Firma J. A. Topf & Soehne, Erfurt.

Auf Ihr Schreiben vom 3. ds. Mts. teilen wir Ihnen mit, daß der Betrieb sich in unserem Krematorium noch nicht so entwickelt hat, um über die Verbrennungsöfen ein Zeugnis ausstellen zu können, wie es für Sie erwünscht ist. Wir können vorläufig nur bestätigen, daß wir mit den gelieferten Öfen zufrieden sind und nach den bisher vorgenommenen 300 Verbrennungen keine wesentliche Abnutzungen festgestellt haben. Infolge der schwachen und ungleichmäßigen Benutzung werden vorläufig für jede Verbrennung noch 100 Kilo Zechenkoks verbraucht. Wir hoffen, daß nach Fertigstellung der ganzen Bauanlage die Benutzung der Öfen eine stärkere werden und damit auch die Brennstoffmenge geringer wird.

Jedenfalls sind wir mit den Öfen so zufrieden, daß wir auf die schon wiederholt an uns gerichteten Anfragen stets empfehlend Auskunft gegeben haben.

Der Stadtgemeindevorstand.
Stadtbauamt.

Ilmenau i. Th., 2. August 1924.

Firma J. A. Topf & Soehne, Erfurt.

Wunschgemäß bestätigen wir Ihnen gern, daß wir mit der von Ihnen im Jahre 1922 errichteten Ofenanlage im hiesigen Krematorium zufrieden sind. Die Anlage hat sich in bezug auf die Vorschriften der Leichenverbrennung und einer sparsamen Wärmewirtschaft sehr gut bewährt. Eine Geruchbelästigung der Anwohner ist bei sachgemäßer Bedienung des Ofens bis heute noch nicht eingetreten. Trotz teilweiser starker Inanspruchnahme des Ofens haben sich bisher keine Mängel an der Anlage gezeigt.

gez.: Unterschrift.

Verein für Feuerbestattung e. V.,
Suhl

Suhl, 20. Oktober 1923.

Firma J. A. Topf & Soehne, Erfurt.

Wir bestätigen gern, daß wir mit der von Ihrer Firma in unserem Krematorium ausgeführten Anlage in technischer Hinsicht zufrieden sind. Der Ofen arbeitet gut und bedarf eines verhältnismäßig geringen Koksverbrauches. Die Arbeitsweise der Saugzuganlage ist vorzüglich und mit dieser verbunden betätigt sich auch der Schornstein besonders befriedigend. Die Ausführung der ganzen Einäscherungsanlage ist in exakter Weise erledigt worden.

gez.: Unterschrift.

Magistrat
zu Hirschberg i. Schl.

Hirschberg, 26. Mai 1923.

Firma J. A. Topf & Soehne, Erfurt.

Auf Ihr Schreiben vom 19. ds. Mts. bestätigen wir Ihnen, daß der im Jahre 1914 gelieferte Einäscherungsofen zur Zufriedenheit arbeitet.

Die Bedienung ist bequem und einfach. Die Konstruktion hat sich gut bewährt. Bezüglich der Ausführung haben sich bis jetzt keine Mängel gezeigt.

An Koks werden verbraucht:

Für die erste Einäscherung		5	Zentner
" " zweite	"	3	"
" " dritte	"	1	"
" " vierte	"	—	"

Die Einäscherungsdauer beträgt ca. 1½ Stunde. Für die Hochheizung sind 2—3 Stunden erforderlich. Der Generatorschieber wird bei einmaliger Hochheizung geschlossen. Da aber bei Dauereinäscherungen bei jeder weiteren Einäscherung Nachschüttungen erfolgen müssen, muß auch der Generatorenschieber geöffnet werden.

Betreff
Einäscherungsofen.

Es wird Ihnen hiermit bestätigt, dass Herr Obering. Klettner den vorgesehenen Umbau des Einäscherungsofens in 2 1/2 Wochen durchgeführt und hierbei Verbesserungen nach Ihren neuesten Erfahrungen berücksichtigt hat.
Herr Klettner hat den Ofen im Betrieb vorgeführt und nach dreitägigem Probebetrieb mit insgesamt 15 Einäscherungen zu unserer vollen Zufriedenheit heute übergeben.
Die Leistung des Ofens, insbesondere hinsichtlich des erforderlichen Brennstoffverbrauches, übertraf alle Erwartungen. Am dritten Tage nach Inbetriebnahme wurden bereits Einäscherungszeiten von 40 Minuten erzielt ohne jeglichen Brennstoffverbrauch ausser dem für das Anheizen erforderlichen.

Es steht Ihnen frei, den Ofen Interessenten nach vorheriger rechtzeitiger Anmeldung vorzuführen.

Eine Veröffentlichung vorstehenden Schreibens ohne vorherige diesseitige Genehmigung ist nicht gestattet.

Im Auftrage:
Hail

Document 137: Letter from the municipal administration of Wiesbaden to the Topf Company of 19 December 1949 regarding improvement work done by chief engineer Klettner. Document kindly submitted by J.M. Boisdefeu.

An die Stadtkommandantur, Oberlt. Proskurin 6.4.48 -2-

Äscherungsöfen sind in jedem Falle in Verbindung mit den be stehenden Friedhofsanlagen bezw. Einäscherungshallen eingerichtet worden.

Diese Gesichtspunkte gelten in der heutigen Zeit mehr denn je, was das grosse Interesse aller Stadtverwaltungen an den Einäscherungsöfen beweist.

Bezüglich des Falles Wiesbaden teilen wir Ihnen mit, dass Lieferungen von unserem Werke n i c h t erfolgen, die Anlage wird nur nach unserem Plan gebaut. Wir haben im Februar dieses Jahres eine vorläufige Bauzeichnung angefertigt, die aber eine Änderung erfahren hat. Die endgültige Bauzeichnung wird gegenwärtig ausgearbeitet. Irgendwelche Zeichnungen zu diesem Bauvorhaben sind bei uns n i c h t in den Betrieb gegeben und ist dieses auch garnicht notwendig, weil unser Erfurter Werk für eine Fabrikation n i c h t in Anspruch genommen wird. Alle Lieferungen und Fertigungen sind aus der Westzone vorgesehen. Unsere Leistung besteht also in diesem Falle in der Ingenieurarbeit. Es liegt ein Bestellschreiben der Stadtverwaltung in Wiesbaden vor, das aber nicht endgültig ist. Von uns aus ist das Geschäft noch nicht verbucht und auch die Auftragsannahme noch nicht schriftlich bestäti

Die Bearbeitung dieses Projektes ist bei uns eine rein kommerzielle Angelegenheit, da wir auf Verdienst zur Aufrechterhaltung unserer Firma angewiesen sind und bei Ablehnung unsere Firma mit dem Projekt eine Konkurrenzfirma -wahrscheinlich aus dem Westen - beauftragt würde mit dem Resultat, dass das Geschäft unserer Firma und damit der Ostzone verloren geht.

Den Einäscherungsofenbau bearbeiten in erster Linie der Techniker Günter Mann unter Leitung von Herrn Ingenieur Hans Streichardt.

Eine Verpflichtung zur Meldung derartiger Aufträge, gleich sie aus der Ost- oder Westzone stammen, oder die Einhaltung

-b.w.-

DEUTSCHES REICH

Eigentum des Reichspatentamts

AUSGEGEBEN
AM 24. AUGUST 1920

REICHSPATENTAMT

PATENTSCHRIFT

— № 324252 —

KLASSE 24 d Gr. 1

J. A. Topf & Söhne in Erfurt.

Sargeinführvorrichtung für Verbrennungsöfen mit heb- und senkbarem Fahrgestell für den Sargträger.

Patentiert im Deutschen Reiche vom 24. April 1915 ab.

Die Erfindung bezieht sich auf Sargeinführvorrichtungen, bei denen ein heb- und senkbares Fahrgestell für den zur Einführung in den Ofen dienenden Sargträger zur Verwendung kommt. Sie bezweckt eine Erhöhung der Betriebssicherheit derartiger Vorrichtungen durch Anwendung möglichst einfacher und sicher wirkender Antriebsmittel, die von einer einzigen Antriebswelle aus bewegt werden können. Diese Mittel sind im wesentlichen dadurch gekennzeichnet, daß ein entsprechend der Hin- und Rückfahrt des Sargträgers in entgegengesetzten Drehrichtungen bewegtes Antriebsvorgelege einerseits mit einer auf die Fahrgestellhebe- und senkvorrichtung unmittelbar einwirkenden Zahntriebstange, anderseits mit einer Zugvorrichtung verbunden ist, die einen zwischen zwei Anschlägen des fahrbaren Sargträgers hin und her bewegten Mitnehmer besitzt. Diese Teile wirken in der Weise zusammen, daß während der toten Bewegung des Mitnehmers der Zugvorrichtung zwischen den Anschlägen des Sargträgers die Triebstange verschoben und dadurch die Hub- und Senkvorrichtung betätigt wird, jedoch beim Auftreffen des Mitnehmers auf einen der Anschläge und damit bei beginnender Fahrbewegung des Sargträgers die Zahnstange in ihrer jeweiligen Grenzstellung bis zur Beendigung der Fahrbewegung in Ruhe bleibt. Ferner sind auf der Vorgelegeachse durch den Sargträger bewegte Zughebel zum selbsttätigen Öffnen und Schließen der Ofenschieber während der Fahrbewegung angebracht.

Die Zeichnung zeigt in Umrissen ein Ausführungsbeispiel der Erfindung in Fig. 1 in der Seitenansicht und in Fig. 2 und 3 in senkrechten Schnitten nach den Linien *X*-*X* und *x*-*x*, (Fig. 1).

Die Hub- und Senkvorrichtung für das Fahrgestell besteht aus vier paarweise unter dem Fahrgleis *H* angebrachten doppelarmigen Hebeln *K*, deren feste Drehpunkte K^1 sich am Aufstellungsgerüst *A* befinden. Die kürzeren Hebelenden tragen das Gleis, während die längeren durch Gelenke *C* mit der oberen Achse einer Rollenführung R^1 für die Zahntriebstange verbunden sind. Die Rollenführung R^1 ist in einem Gerüstrahmen senkrecht verschiebbar und trägt ein infolge der Hebelverbindung gleichmäßig auf das Fahrgestell einwirkendes Gegengewicht *L*. Ihre Verschiebung und das dadurch mittels der Hebelübertragung bewirkte Heben und Senken des Fahrgestells erfolgt durch eine Triebstange, die als Zahnstange *Q* mit einer winkligen Verlängerung *S* ausgebildet ist. Letztere wirkt als schiefe Ebene für die Rollenführung R^1 und veranlaßt daher beim Verschieben der Stange das Heben oder Senken des Fahrgestells. Die Stange gleitet außerdem an beiden Enden in Gradführungen *R*. Der Antrieb erfolgt in weiter unten näher beschriebener Weise durch die von Hand oder mechanisch betriebene Vor-

Document 150: Patent J.A. Topf & Söhne in Erfurt, No. 324252. "Device for the introduction of the coffin for cremation furnaces with support cart that can be raised and lowered." 24 April 1915. Source: Deutsches Patentamt.

gelegewelle B mittels einer Punktverzahnung P an der die Zugvorrichtung für den fahrbaren Sargträger F betätigenden Vorgelegetrommel T.

Die Zugvorrichtung wird von dem über Rollen M und die Trommel T geführten nachspannbaren Zugglied D gebildet, welches nicht fest mit dem Sargträger F verbunden, sondern frei beweglich durch zwei in bestimmtem Abstande voneinander liegende Schlitze O am Sargträger hindurchgeführt ist. Die Schlitzflächen wirken gleichzeitig als Anschläge für einen zwischen beiden liegenden, am Seil befestigten Mitnehmer N für den Sargträger. Mitnehmer und Anschläge können auch in anderer geeigneter Weise ausgebildet sein. Der Weg, den der Mitnehmer zwischen den beiden Anschlägen zurückzulegen hat, entspricht der Länge der Verschiebung der Triebstange Q, S.

Das Zusammenwirken der Hub- und Senkvorrichtung mit der Zugvorrichtung für den fahrbaren Sargträger geht durch Vermittelung des Vorgeleges wie folgt vor sich: Während die Triebstange durch den Zahntrieb vorgeschoben und infolgedessen unter Senkung der langen Hebelenden K das ganze Fahrgestell angehoben wird (siehe die punktierten Stellungen in Fig. 1), bewegt sich der Mitnehmer N frei zum gegenüberliegenden Anschlag O des Sargträgers. Sobald er auf diesen trifft, ist die Verschiebung der Triebstange zu Ende und wird dadurch aufgehoben, daß die Zähne der Vorgelegetrommel an jedem Ende der entsprechend lang bemessenen Verzahnung Q auf eine lose Zahnfalle q treffen, die durch Ausweichen eine Weiterverschiebung der Stange im gleichen Sinne verhindert, dagegen ein Verschieben im jeweiligen entgegengesetzten Sinne gestattet. Nach Stillsetzung der Stange wird der fahrbare Sargträger F mit Hilfe des gegen den betreffenden Anschlag wirkenden Mitnehmers N in die Ofenöffnung eingefahren und dadurch der Sarg über den Rost der Einäscherungskammer gebracht. Diese Bewegung wird, eben so wie die Rückbewegung, durch Erdanschläge h des Gleises H begrenzt. Nachdem so der Sargträger eingefahren ist, wird das Vorgelege in entgegengesetzter Richtung gedreht, so daß sich der Mitnehmer N wieder frei zum anderen Anschlag O zurückbewegt, während gleichzeitig die Triebstange Q, S zurückverschoben und dadurch unter Hebung der langen Hebelenden K das ganze Fahrgestell gesenkt und hierbei der Sarg auf den Rost gesetzt wird. Inzwischen ist der Mitnehmer zum anderen Anschlag zurückgelangt, so daß, unter Stillsetzung der Triebstange in vorangegebener Weise, der Sargträger wieder in die Anfangsstellung zurückgefahren wird.

Auf der Vorgelegewelle ist lose drehbar noch ein Hebelpaar W mit Rollen V am oberen Ende gelagert. Beim Vorfahren des Sargträgers F werden die Hebel W zur Seite gedrängt, wobei die Rollen V an den unteren Flächen des die Gegengewichte des Sargträgers F tragenden Eisengerüstes entlanggleiten (siehe strichpunktierte Stellung in Fig. 1). Der auf diese Weise hervorgerufene Ausschlag der Hebel W wird durch Seil- oder Kettenzug auf eine Rolle Y übertragen, auf deren Achse Z die Seilscheibe Y^1 zur Bewegung des unter Gewichtswirkung stehenden Seilzuges für die Ofenschieber sitzt. Durch diese Einrichtung wird bewirkt, daß die Ofenschieber mit Beginn des Sargträgervorschubes schnell geöffnet und sofort nach Wiederaustritt des Fahrgestells aus dem Ofen schnell geschlossen werden.

PATENT-ANSPRÜCHE:

1. Sargeinführvorrichtung für Verbrennungsöfen, mit heb- und senkbarem Fahrgestell für den Sargträger, dadurch gekennzeichnet, daß ein entsprechend den Fahrtrichtungen des Sargträgers (F) bewegtes Antriebsvorgelege (B, T, P) durch eine Zahntriebstange (Q, S) auf die Hub- und Senkvorrichtung (R^1, C, K) für das Fahrgestell (H, F) und durch ein, mit einem zwischen Anschlägen (O) des Sargträgers (F) hin und her bewegten Mitnehmer (N) versehenes Zugglied (D) auf den Sargträger (F) einwirkt, derart, daß während der toten Bewegung des Mitnehmers (N) zwischen den Anschlägen (O) die Triebstange (Q, S) verschoben und dadurch die Hub- und Senkvorrichtung (R^1, C, K) in Tätigkeit gesetzt wird, während beim Auftreffen des Mitnehmers (N) auf einen der beiden Anschläge (O) die Triebstange (Q, S) in ihrer jeweiligen Grenzstellung bis zur Beendigung der Fahrbewegung ausgeschaltet wird.

2. Ausführungsform nach Anspruch 1, dadurch gekennzeichnet, daß das Vorgelege (B, T, P) einerseits durch Punktverzahnung (P) auf eine Zahnstange (Q) einwirkt, die mittels einer schrägen Verlängerung (S) eine das Fahrgleis (H) tragende Knickhebelanordnung (K, C) zum Heben und Senken des Gleises bewegt und an den Triebenden beweglichen Zahnflanken (q) zur Begrenzung ihrer Weiterbewegung in gleicher Richtung besitzt, anderseits mit einer Zugvorrichtung (T, D) verbunden ist, deren Seil oder Kette (D) einen Mitnehmer (N) trägt, der sich während der Bewegung der Hubvorrichtung (R^1, C, K) leer zwischen zwei Anschlägen (O) des Sargträgers (F) bewegt.

3. Ausführungsform nach Anspruch 1 und 2, dadurch gekennzeichnet, daß auf der Vorgelegeachse (B) lose drehbar ein

Document 150: continued.

oder mehrere Hebel (*W*, *V*) angebracht sind, die durch eine Zugvorrichtung (*Y*, *Y*¹) mit den Ofenschiebern in Verbindung stehen und durch den Sargträger (*F*) bzw. das Fahrgestell bewegt werden, um während des Sargeinführens kurz vor Eintritt des Sarges in den Ofen das schnelle Öffnen und gleich nach Wiederaustritt des Sargträgers aus dem Ofen das schnelle Schließen der Schieber selbsttätig zu bewirken.

J. A. Topf & Soehne in Erfurt

Vorrichtung zum Nachverbrennen der Rückstände in Leichenverbrennungsöfen

Patentiert im Deutschen Reiche vom 24. März 1929 ab

Die Erfindung bezieht sich auf eine Vorrichtung zum Nachverbrennen der Rückstände in Leichenverbrennungsöfen, hauptsächlich zu dem Zweck, die mit der Leichenasche sich mischende Holzasche zu verbrennen. Von bekannten Nachverbrennungseinrichtungen unterscheidet sich der Erfindungsgegenstand dadurch, daß der am Ende der geneigten Sohle des Aschenfalls angeordnete, herausnehmbare Sammelbehälter für die Verbrennungsrückstände mit einem Siebboden versehen und über der Mündung einer regelbaren Verbrennungsluftzuleitung aufgestellt ist. Diese Anordnung besitzt den Vorzug der Einfachheit. Des weiteren ist über dem Sammelbehälter unterhalb der seitlichen Gasabzüge ein den Aschenfall des Ofens gegen den Behälter absperrender gasdurchlässiger Schieber angeordnet, wodurch bei unmittelbar aufeinanderfolgenden Einäscherungen die währenddessen im Sammelbehälter noch der Nachverbrennung ausgesetzten Rückstände von denen der nächsten Einäscherung getrennt gehalten werden können.

Die Zeichnung zeigt schematisch ein Ausführungsbeispiel in Abb. 1 im Längsschnitt durch den Ofen. Abb. 2 ist eine Stirnansicht der zur Nachverbrennung dienenden Vorrichtung.

Am Vorderende des Ofens ist unterhalb des Aschenfalls *f* ein Behälter *a* eingebaut, der mit einem Siebboden *b* und einer unterhalb desselben einmündenden Verbrennungsluftzuleitung *c* versehen ist. Letztere ist durch Klappen *d* o. dgl. regelbar.

Die Verbrennungsrückstände werden kurz vor Beendigung des Einäscherungsvorganges in den Behälter *a* eingeholt und unterliegen dort einer Nachverbrennung, wobei die Abgase durch die seitlichen Abzüge *g* des Ofens entweichen.

Damit in den Behälter *a* nicht zugleich die Rückstände aus zwei aufeinanderfolgenden Einäscherungen gelangen können, ist über dem Behälter *a* unterhalb der Abzüge *g* eine ausziehbare Absperrplatte *e* angebracht, durch die der Behälter gegen den Aschenfall *f* abgeschlossen werden kann. Diese Platte ist gasdurchlässig, z. B. fein gelocht, in der Weise, daß wohl die Nachverbrennungsgase abziehen, aber keine Rückstände aus dem Aschenfall *f* in den Behälter *a* gelangen können. Infolgedessen kann mit einer weiteren Einäscherung begonnen werden, bevor die Nachverbrennung der Rückstände aus der vorhergehenden Einäscherung im Behälter *a* beendet ist.

PATENTANSPRÜCHE:

1. Vorrichtung zum Nachverbrennen der Rückstände in Leichenverbrennungsöfen, dadurch gekennzeichnet, daß der am Ende der geneigten Sohle des Aschenfalls (*f*) angeordnete, herausnehmbare Sammelbehälter (*a*) mit einem Siebboden (*b*) versehen und über der Mündung einer regelbaren Verbrennungsluftzuleitung (*c, d*) aufgestellt ist.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß über dem Sammelbehälter unterhalb der seitlichen Gasabzüge (*g*) ein den Aschenfall des Ofens gegen den Behälter absperrender gasdurchlässiger Schieber (*e*) angeordnet ist.

Viktor Quehl in Gera

Feuerbestattungsofen mit drehbaren Rosten

Patentiert im Deutschen Reiche vom 15. April 1931 ab

Bei den bisherigen Feuerbestattungsöfen sind die den Sarg und die einzuäschernden Leichenteile tragenden Ofenteile — der Muffel- und der Aschenrost — als feststehende Ofenteile ausgeführt.

Dies hat den Nachteil, daß die Leichenteile nach ihrer Einäscherung mittels eines Kratzgerätes von diesen Ofenflächen heruntergescharrt werden müssen. Ein derartiges Eingreifen in den Einäscherungsvorgang entspricht nicht einer würdigen Form der Feuerbestattung. Weiterhin wird beim Einbringen des Kratzgerätes in den Ofen durch das Öffnen von Türen ein beträchtlicher Wärmeverlust durch die einströmende kalte Luft hervorgerufen. Auch treten leicht Beschädigungen des glühenden Mauerwerkes durch die eisernen Kratzgeräte ein.

Nach der Erfindung wird die Anwendung von Kratz- und Schürgeräten dadurch vermieden, daß der den Sarg tragende Muffelrost und der dazugehörige Aschenrost von außen schwenkbar um eine oder mehrere Achsen angeordnet sind, wobei die Roste in mehrere einzeln abschwenkbare Flächen mit beliebiger Achsenanordnung unterteilt sein können.

Es ist dadurch die Möglichkeit gegeben, ohne Zuhilfenahme von Kratz- und Schürgeräten je nach Fortgang der Einäscherung die verbleibenden Einäscherungsreste von außen ohne Öffnen des Ofens durch einfaches Abschwenken der Flächen ganz oder teilweise von dem Muffelrost und dem Aschenrost zu entfernen.

In der Zeichnung ist ein Ausführungsbeispiel der Erfindung dargestellt. Es sind bezeichnet mit *m* der um eine Achse *e* drehbare Muffelrost, mit *b* der in einzelne, für sich schwenkbare Flächen *f* unterteilte Aschenrost, wobei die Flächen *f* um die Einzelachsen *e* geschwenkt werden können.

Der Erfindungsgegenstand kann in einzelnen Teilen auch anders ausgebildet sein, solange das Wesen der Erfindung, die drehbare Ausbildung des Muffel- und des Aschenrostes, gewahrt bleibt.

PATENTANSPRÜCHE:

1. Feuerbestattungsofen mit drehbaren Rosten, dadurch gekennzeichnet, daß der den Sarg und die einzuäschernden Teile tragende Muffelrost und der Aschenrost von außen schwenkbar angeordnet sind.

2. Feuerbestattungsofen nach Anspruch 1, dadurch gekennzeichnet, daß der Muffelrost und der Aschenrost in mehrere einzeln abschwenkbare Flächen unterteilt sind.

Einäscherungsofen

Patentiert im Deutschen Reiche vom 9. September 1933 ab

Gegenstand der vorliegenden Neuerung ist eine Einrichtung an Einäscherungsöfen, und es soll damit u. a. erreicht werden, daß durch eine besondere Zuführung der Verbrennungsluft die Verbrennung verbessert wird.

Das Zuführen der Luft bei Einäscherungsöfen mit Rost oder geschlossener Grundplatte ist bekanntlich mit Mängeln verbunden, und zwar sind diese Mängel durch die Feuerführung im Einäscherungsraum begründet, die sich aus der konstruktiven Gestaltung der Platte oder des Rostes ergibt. Die Grundplatte hat infolge ihrer Geschlossenheit den Vorteil der Wärmespeicherung. Sie hat aber dabei den großen Nachteil, daß die Verbrennungsluft nicht zu den mittleren Teilen des Verbrennungsgutes gelangen kann, weil der Zerfall desselben nur außen stattfindet, wo der Sauerstoff Zutritt hat. Da der Sarg mit seinen mittleren Teilen fest auf der Grundplatte aufliegt, ist dort die Verbrennung eine unvollkommene bzw. verlangsamte. Diesen Nachteil vermeidet der Rost. Hiermit ist es möglich, die Luft auch zur Mitte des verbrennenden Sarges zu leiten und damit die Einäscherung zu beschleunigen. Aber auch hierbei zeigten sich Nachteile:

1. Weil der Rost offen ist, werden die Strömungsverhältnisse der Heizgase in der Muffel nicht mehr beherrscht,

2. während der Einäscherung der mittleren, schwerer verbrennenden Teile des Einäscherungsgutes strömt weiterhin durch die seitlichen Öffnungen des Rostes nutzlos Luft zu, die den Ofen abkühlt,

3. der Rost hat eine geringe Wärmespeicherfähigkeit.

Man hat indessen auch Öfen mit geschlossener Grundplatte gebaut, bei denen die Zuführung der Verbrennungsluft mittels Düsen geschieht, die von der Seite wie von oben auf den Verbrennungsgegenstand gerichtet sind.

Diese Art der Luftzuführung ist schon erheblich wirksamer, jedoch besteht auch hier der Nachteil, daß der Einäscherungsgegenstand zunächst nur oben und an den Seiten von der Verbrennungsluft umspült wird, die Luftzuführung an der Unterseite des Einäscherungsgegenstandes fehlt dagegen. Gerade an dieser Stelle ist aber die Luftzuführung besonders wirksam, weil die dort entstehenden Flammen um den ganzen Einäscherungsgegenstand herumschlagen und diesen so in Flammen vollkommen einhüllen.

Die Erfindung sieht daher vor, die Verbrennungsluft durch in der Grundplatte angebrachte Düsen zuzuführen. Die Grundplatte ist deshalb mit talförmigen Vertiefungen ausgerüstet, so daß sie eine rostartige Oberfläche erhält. In die Vertiefungen zwischen den Rostbalken münden die Luftdüsen.

Zweckmäßig wird die Bodenplatte aus einzelnen Steinen aufgebaut, die durch ihre Form und in ihrer Gesamtheit der Platte die rostartige Gestalt geben. Zwecks Unterbringung der Preßluftleitungen versieht man die Steine innen mit einer Aushöhlung. Die Luftzuführung zu den Düsen kann so ausgebildet sein, daß jede Düse einzeln regelbar ist. Auch

Document 153: Patent Wilhelm Basse in Hamburg, No. 638582, transferred to J.A. Topf & Söhne on 27 November 1937. "Incineration furnace." Source: Deutsches Patentamt.

638 582

kann man die Düsen zu diesem Zweck zu Gruppen zusammenfassen.

Bei der Anordnung nach der Erfindung erzeugt die ausströmende Preßluft unter dem Sarg eine kräftige Flammenbildung, wodurch die Rostplatte die stärkste Beheizung erfährt und die Wärme infolge der geschlossenen Ausführung der Bodenplatte gut gespeichert wird. Letzteres ist insofern von Wichtigkeit, als hierdurch die Dauer der nachfolgenden Einäscherungen wesentlich abgekürzt wird.

In der Zeichnung ist ein Ausführungsbeispiel dargestellt.

Fig. 1 ist ein senkrechter Schnitt durch den Ofen, und

Fig. 2 ist eine Draufsicht auf die Grundplatte.

Es bezeichnen darin *a* die die Rostplatte bildenden Steine, *b* den Unterbau der Ofenkonstruktion, *c* die Muffelwände, *d*, d_1 die Preßluftleitungen, *e* die dazugehörigen Konusabdichtungen, *f* die in den Steinen ausgesparten Luftkanäle, *g* die zum Ausströmen der Luft bestimmten Düsenlöcher.

In Fig. 2 sind die Steine mit den Ziffern 1 bis 20 bezeichnet.

Die Formsteine sind in der hier gezeigten Ausführungsart zu beiden Seiten dachförmig abgeschrägt, so daß hierdurch die rostartige Gestalt der Bodenplatte erzeugt wird. In die talförmigen Vertiefungen zwischen den einzelnen Steinen münden die in letzteren angebrachten Luftdüsen, und zwar sind diese so eingerichtet, daß die ausströmende Luft unmittelbar auf den Verbrennungsgegenstand trifft. Hierin liegt die Erzielung der wirksamsten und zugleich sparsamsten Ausnutzung der Verbrennungsluft. Die Luftdüsen sind überdies zweckmäßig versetzt zueinander angeordnet, so daß die Luftzufuhr zum Brenngut eine vollkommene und gleichmäßige ist.

Die Einrichtung bietet noch den Vorteil, daß infolge der an den schräg liegenden Teilflächen der Rostplatte befindlichen Mündungen der Düsen einer etwa durch das darüberliegende Brenngut entstehenden Verstopfung vorgebeugt wird. Die Lage der Düsen kommt insofern noch zu statten, als man dieselben bei der Aschenentnahme sämtlich anstellen und damit die feine Flugasche, die dann vom Schornsteinzug angesogen wird, fortblasen kann.

Die in den Steinen befindliche kanalartige Aushöhlung *f* kann sich (Fig. 2) auf die Länge nur eines Steines, wie z. B. bei Stein 6 und 10, erstrecken, jedoch auch zugleich auf mehrere Steine, wie etwa bei Stein 1 und 5 bzw. Stein 13 und 17.

Als Preßluftzuleitung kann in jedem dieser Fälle nur eine einzige Leitung d_1 dienen, während natürlich jeder einzelne Stein noch seinen eigenen Anschluß an die Luftzuleitung haben muß.

Die einfach herzustellenden Formsteine können bei etwaiger Ausbesserung, bedingt durch Abbrand oder mechanische Beschädigung (Absetzen des Sarges), leicht einzeln ausgewechselt werden, ohne daß der Verband der Rostplatte dadurch gelockert wird.

PATENTANSPRÜCHE:

1. Einäscherungsofen mit den Einäscherungsraum unten abschließender Bodenplatte und mit Luftdüsen, die auf den Einäscherungsgegenstand gerichtet sind, dadurch gekennzeichnet, daß die aus Formsteinen (*a*) bestehende Bodenplatte eine rostartige Oberfläche besitzt, und daß in die Vertiefungen zwischen den Rostbalken die Luftdüsen (*g*) münden.

2. Einäscherungsofen nach Anspruch 1, dadurch gekennzeichnet, daß die Formsteine (*a*) zwecks Unterbringung der Preßluftleitungen (*f*) hohl ausgebildet sind.

3. Einäscherungsofen nach Anspruch 1 und 2, dadurch gekennzeichnet, daß die Luftdüsen (*g*) einzeln oder gruppenweise regelbar angeordnet sind.

659 405

J. A. Topf & Söhne in Erfurt

Beschickungseinrichtung für Einäscherungsöfen

Patentiert im Deutschen Reiche vom 20. November 1936 ab

Gegenstand der Erfindung ist eine Beschickungseinrichtung für Einäscherungsöfen mit am Sargeinführungswagen befestigter Sargtragplatte, durch die alle Mängel, die zur Zeit sowohl hinsichtlich der Vorbereitung als auch der Ausführung der Sargeinführung bestehen, beseitigt werden sollen. Durch die Erfindung kommen in Fortfall:

1. das Auflegen von Holzlatten oder Eisenstäben auf die Tragarme des Wagens,

2. das Aussparen der Roststeine für die Tragarme des Wagens,

3. das Entfernen der Sargfüße vor der Einführung des Sarges in den Ofen,

4. das Festhalten des Sarges (beim Herausziehen der Tragplatte aus dem Ofen) durch dahintergelegte Stempel, gleich welcher Art, mechanisch oder von Hand.

Die Erfindung ist im wesentlichen dadurch gekennzeichnet, daß mit dem Wagen eine Sargtragplatte verbunden ist, auf der eine zweite, verschiebbare Platte angeordnet ist, die bei Einführung des Sarges das hintere Sargende stützt und sowohl ein erschütterungsfreies Absetzen des Sarges auf dem Rost als auch das freie Herausziehen der Tragplatte ermöglicht.

Die Zeichnung zeigt ein Ausführungsbeispiel in Abb. 1 in Ansicht, Abb. 2 ist ein Querschnitt durch die beiden Tragplatten. Abb. 3 bis 6 zeigen schematisch den Vorgang der Sargeinführung und der Entfernung der Tragplatte aus dem Ofen.

Mit einem von Hand bewegbaren Wagen *a* ist in bekannter Weise eine heb- und senkbare längere Sargtragplatte *b* fest verbunden, die eine zweite auf ihr verschiebbare kürzere Platte *c* trägt. Das Vorderende *g* der Hauptragplatte *b* ist unter Beibehaltung einer ebenen Oberfläche so gestaltet, daß es nicht unter der Hilfsplatte *c* hindurchgezogen werden kann.

Der Sarg wird so auf die Platten gestellt, daß der hintere Sargteil *d* auf die obere Platte *c* zu stehen kommt, während der Vorderteil *e* etwas über die Hauptragplatte *b* übersteht (Abb. 3). In dieser Lage wird der Sarg in den Ofen eingefahren (Abb. 4). Darauf wird die Platte *b* gesenkt, bis sie sich dicht über dem Ofenrost *f* befindet und der Vorderteil des Sarges sich auf den Rost stützt (Abb. 5). Bei dem nun folgenden Herausziehen der Tragplatte *b* aus dem Ofen bleibt die Lage der Hilfsplatte *c* infolge des auf ihr ruhenden Gewichts des hinteren Sargendes unverändert, bis sie durch das vordere Ende *g* der Platte *b* nach vorn gezogen und dadurch aus dem Ofen mit herausgenommen wird (Abb. 6). Da die Platte *c* nur dünn ist, macht das hintere Sargende beim Hervorziehen der Platte nur eine ganz geringe Senkbewegung. Der Sarg wird also im ganzen ohne Erschütterung auf den glatten Rost aufgesetzt.

PATENTANSPRUCH:

Beschickungseinrichtung für Einäscherungsöfen mit am Sargeinführungswagen befestigter Sargtragplatte, dadurch gekennzeichnet, daß auf der Tragplatte (*b*) verschiebbar eine kürzere Platte (*c*) angeordnet ist, die beim Einfahren und Absetzen des Sarges auf den Rost das hintere Sargende stützt und beim Zurückziehen der Platte (*b*) durch deren vorderes Ende (*g*) mit herausgenommen wird.

Beschreibung

(Anlage 2 zum heutigen Antrag)

Kontinuierlich arbeitender Leichen-Verbrennungsofen für Massenbetrieb.

In den durch den Krieg und seine Folgen bedingten Sammellagern der besetzten Ostgebiete mit ihrer unvermeidbar hohen Sterblichkeit ist die Erdbestattung der großen Menge verstorbener Lagerinsassen nicht durchführbar. Einerseits aus Mangel an Platz und Personal, andererseits wegen der Gefahr, die der näheren und weiteren Umgebung durch die Erdbestattung der vielfach an Infektionskrankheiten Verstorbenen unmittelbar und mittelbar droht.

Es besteht daher der Zwang, die stündig anfallende große Anzahl von Leichen durch Einäscherung schnell, sicher und hygienisch einwandfrei zu beseitigen. Dabei kann natürlich nicht nach den für das reichsdeutsche Gebiet geltenden gesetzlichen Bestimmungen verfahren werden. Es kann also nicht jeweilig nur 1 Leiche eingeäschert und der Einäscherungsprozeß kann nicht ohne Nach- und Zusatzbeheizung durchgeführt werden. Vielmehr müssen fortlaufend gleichzeitig mehrere Leichen gemeinsam eingeäschert werden und während der Gesamtdauer des Einäscherungsprozesses müssen die Flammen und die Feuergase auf die einzuäschernden Leichen unmittelbar einwirken. Eine Scheidung der Asche der mehreren, gleichzeitig Eingeäscherten kann nicht erfolgen, die Leichenasche kann nur gemeinsam verwahrt werden. Man kann somit bei den Vorrichtungen, die nur vorgeschilderten Beseitigung der Leichen dienen, nicht von einer "Einäscherung" sprechen, sondern es handelt sich tatsächlich um eine Leichenverbrennung.

Zur Durchführung dieser Verbrennung - und zwar auch schon nach vorgeschilderten Gesichtspunkten - wurden bisher in einzelnen derartigen Lagern eine Anzahl Mehrfach-Muffel-Öfen aufgestellt, die naturgemäß periodisch beschickt werden und arbeiten

- 2 -

Document 155: J.A. Topf & Söhne in Erfurt, patent application for "Continually operating corpse-combustion furnace for large-scale operation." 4 November 1942. Source: Deutsches Patentamt.

J.A.TOPF & SÖHNE ERFURT TAG 4.11.42 BLATT 2

Reichspatentamt, Berlin SW 61

~~102805~~ 2,7.16

Infolgedessen befriedigen diese Öfen noch nicht voll, denn die Verbrennung geht in diesen noch nicht schnell genug vor sich, um die laufend anfallende grosse Anzahl von Leichen in möglichst kurzer Zeit zu beseitigen.

Letzteres kann nur geschehen durch Öfen, die kontinuierlich beschickt werden können und dann ebenso arbeiten. Zu denken wäre z.B. an solche in Form von Tunnel-Öfen. Bei diesen würden die zu verbrennenden Leichen je am vorderen Ende eines langgestreckten inwendig beheizten Tunnels auf eine bewegte Auflageverrichtung aufgegeben werden, die sich in der Längsrichtung durch den Ofen hindurchbewegt, dabei die Leichen durch eine Anheiz-Zone in die Verbrennungs-Zone führt und am hinteren Ende des Ofens die Leichenasche austrägt. Einer solchen Konstruktion steht aber die bei anderen Gelegenheiten oft festgestellte Schwierigkeit entgegen, zu bewegende Metallteile, die der Einwirkung von Feuer oder Rauchgasen ausgesetzt sind, auf die Dauer beweglich zu erhalten, auch wenn - wie im vorliegenden Fall - die bewegten Teile soweit als irgend möglich mit Schamotte- oder sonstigem feuerfestem Material verkleidet würden. Außerdem bereitet es Erschwernisse, bei Feuerungsanlagen, die - wie auch im angenommenen Fall - mit Zug, also mit verschiedenem Luft- bezw. Gasdruck in den einzelnen Teilen arbeiten, die bewegten Teile gegen die feststehenden so wie notwendig abzudichten. Ferner wäre ein ständiger Kraftbedarf zum Antrieb der bewegten Auflageverrichtung notwendig. Schließlich wäre auch die Anordnung der Rauchgaszüge usw. unerträglich, so daß aus allen vorgenannten Gründen Tunnel-Öfen für Leichenverbrennung nicht zu empfehlen sind.

Um die vorgenannten Nachteile von Muffel- und Tunnel-Öfen zu vermeiden, dagegen aber alle Vorteile der kontinuierlichen Beschickung und Arbeitsweise auch bei Leichenverbrennungsöfen, verbunden mit bestmöglicher Ausnutzung des erforderlichen Brennmaterials, zu erreichen, schlägt die Erfindung einen kontinuierlich arbeitenden Ofen vor, bei welchem unter Fortfall von im Feuer zu bewegenden Konstruktionsteilen die Fortbewegung der am oberen Ende des

- 3 -

Document 155: continued.

J.A.TOPF & SÖHNE ERFURT

TAG 4.11.42 BLATT 3

Reichspatentamt, Berlin NW 61

2717 ~~702806~~

Ofens eingeführten Leichen innerhalb des Ofens selbsttätig erfolgt. Die Leichen gleiten durch eigene Schwerkraft auf entsprechend geneigten und geformten Unterlagen in den beheizten Ofen hinein und dann weiter herab, geraten auf diesem Wege ins Brennen, um schließlich an geeigneter Stelle des Ofeninneren auszubrennen und zu verascheh.

Fig.1 zeigt ein Ausführungsbeispiel in senkrechtem Schnitt, Fig.2 ist ein Schnitt nach A-B, Fig.1.

Die Erfindung sieht beispielsweise einen Ofen mit mehreren in der Längsrichtung gegen die Waagerechte geneigten inneren Gleitbahnen vor - in der Zeichnung sind davon drei a, a1, a2 angenommen -, die sick-sack-artig aufeinander folgen. Jede Gleitbahn besteht aus mehreren Schamotte-Längsbäken b, die zur besseren Haltbarkeit durch darunter angeordnete Gewölberippen c unterstützt sind. Zwischen den Schamotte-Längsbalken b sind Quertragsteine d angeordnet, so daß jede Gleitbahnfläche rostartig ausgebildet ist. Die Schamotte-Längsbalken b lagern mit ihrem oberen Ende im Umfassungsmauerwerk e des Ofens, mit dem unteren in entsprechenden Schamotte-Mauerwerk-Querbögen f. Die oberen Gleitbahnen sind je von einem in der Längsrichtung ebenfalls gegen die Waagerechte geneigten Deckengewölbe g überspannt, das mit Durchbruchsöffnungen versehen ist. Die Abdeckung über dem vorderen Teil der obersten Gleitbahn erhält keine Durchbruchsöffnungen.

Oben, wo am Ofen eine entsprechende Plattform h oder dergl. angeordnet ist, befindet sich am Anfang der obersten Gleitbahn a eine genügend weite Einführöffnung i, die normalerweise stets durch eine in den Vorraum ausweichende, selbstschließende Klapptür k verschlossen ist. Durch diese Einführöffnung werden die zu verbrennenden Leichen quer zur Längsrichtung des Körpers auf die oberste Gleitbahn a aufgegeben. Um diese Queraufgabe zu ermöglichen, ist der Ofen mit entsprechender lichter Weite ausgeführt. Die seitlichen Abstände der Einführung der

- 4 -

TAG 4.11.42 BLATT 4

Reichspatentamt, Berlin SW 61

einzelnen zu verbrennenden Leichen in den Ofen richten sich nach dem Ablauf der Gesamtverbrennung, die ja durch die Eigenart des Ofens möglichst beschleunigt werden soll.

Am unteren Ende der ersten Gleitbahn a schließt sich an der Umkehrstelle in entgegengesetzter Neigung die zweite Gleitbahn a1 an, an diese die nächste a2 und am Fuße der letzten ist der waagerecht liegende Schamotte-Ausbrennrost l mit der darunter vorgesehenen Asche-Sammelkammer m angeordnet. Vor diesem Ausbrennrost wird die Feuerung n untergebracht, die entweder als Planrost-, Treppenrost-, Generator-, Gas-, Öl- oder sonstiger Feuerung ausgeführt werden kann, je nach dem Brennmaterial, welches verheizt werden muß. Die Flammen- bezw. Heizgasführung ist so angeordnet, daß sowohl der Ausbrennrost l als auch die bestartig ausgebildeten Gleitbahnen a, a1, a2 und alle durchbrochenen Deckengewölbe g den Flammen und Heizgasen den Durchgang von unten nach oben ermöglichen. Am oberen Ende des Ofens, der Einführöffnung i gegenüber, liegt die Austrittsöffnung o für die abzuleitenden Rauchgase, die dort in geeigneter Weise in den Schornstein p eintreten. Die Rauchgase können natürlich vor dem Eintritt in den Schornstein auch erst durch einen in der Zeichnung nicht mit dargestellten Rauchgas-Luftvorwärmer entsprechender Bauart geleitet werden, um die darin enthaltene Wärme zum Vorwärmen der Verbrennungsluft auszunutzen.

Die zu verbrennenden Leichen sind also auf ihrem Weg durch den Ofen ständig den Einwirkungen der ihrer Bewegungsrichtung entgegenströmenden Flammen bezw. Heizgasen ausgesetzt. Durch seitlich verschiebbare und ebenso bedienbare, an den Umkehrstellen unter dem unteren Ende der oberen Gleitbahnen a, a1, angeordnete mehrteilige Schamotte-Schieber q kann eine Hemmung oder Unterbrechung des Leichendurchganges durch den Ofen erfolgen. Ferner kann durch entsprechend angeordnete Handstoß-Öffnungen r bei einem evtl. Festbacken oder Festkleben der Verbrennungsobjekte von außen nachgeholfen werden. Asche, die beim Verbrennungsvorgang innerhalb des Ofens anfällt, soll

- 5 -

TAG 4.11.42 BLATT 5

EMPFÄNGER

Reichspatentamt, Berlin SW 61

2717

soweit wie möglich durch die Öffnungen der Gleitbahnen a, a1, a2, und Deckengewölbe g nach unten bis zur Asche-Sammelkammer m durchfallen. Asche, die sich unterwegs evtl. auf der Rückseite von Mauerwerksteilen der durchbrochenen Deckengewölbe g oder sonstwo absetzt, kann durch entsprechende Asche-Reinigungsöffnungen s nach außen abgezogen werden. Die Hauptasche sammelt sich unter dem Ausbrennrost l der schon erwähnten Asche-Sammelkammer m wo sie an ihrer Oberfläche auch dauernd der Einwirkung der Feuergase unterliegt, so daß evtl. noch nicht ganz ausgebrannte Reste der Verbrennungsobjekte auch in diesem Aschenraum noch nach- und ausbrennen können. Durch entsprechend angeordnete, nach dem Ofeninneren offene Luftzuführungskanäle t wird auf dem gesamten Wege der Verbrennungsobjekte durch den Ofen für ausreichende Zufuhr von Luft zur Förderung des Verbrennungsvorganges der Leichen gesorgt. Diese Luft kann vor dem Eintritt in das Ofeninnere auch in einem in der Zeichnung nicht mit dargestellten Rauchgas-Luftvorwärmer vorgewärmt werden. Die Zufuhr sowohl der kalten als auch der vorgewärmten Luft kann auch unter Druck erfolgen, um eine ständige gute Durchwirbelung der Rauchgase zu erreichen.

Der Ofen kann an den Stellen, wo in der Zeichnung Fig.1 Nachstoßöffnungen r angeordnet sind, auch mit je noch einer Einführöffnung i mit selbstschließender Klapptür k versehen werden, um - von dort anzuordnenden Plattformen aus - den Ofen auch nur teilweise beschicken zu betreiben zu können, wobei je nach dem Umfang des Teilbetriebes der eine oder beide mehrteilige Schamotte-Schieber q geschlossen werden.

J. A. Topf & Soehne in Erfurt

Ausfahrbarer Schlackenrost für mit Unterwind betriebene Feuerungen

Patentiert im Deutschen Reiche vom 22. August 1928 ab

Für Unterwindfeuerungen mit hoher Brennleistung ist es besonders wichtig, daß diese auch während des Abschlackens des Rostes erhalten bleibt. Dies ist aber nur dann möglich, wenn der Verbrennungsvorgang auch während des Abschlackens nicht gestört wird, was eintritt, wenn der Unterwind während des Abschlackens abgestellt werden muß.

Gegenstand der Erfindung ist ein ausfahrbarer Schlackenrost, welcher ein schnelles Abschlacken während des Betriebes gestattet, ohne daß hierbei der Unterwind abgestellt zu werden braucht. Zu diesem Zweck ist am hinteren Ende des ausfahrbaren Schlackenrostes eine Abschlußplatte angelenkt. Durch das Ausfahren des Schlackenrostes, welches von Hand oder mechanisch erfolgen kann, wird am hinteren Rostende ein breiter Spalt freigelegt, durch welchen hindurch die Rückstände schnell in den unterhalb des Schlackenplanrostes befindlichen Schlackenschacht abstürzen können, wobei sie über die dabei schräg stehende Abschlußplatte abrutschen. Diese Abschlußplatte verhindert hierbei ein unmittelbares Überströmen von Luft aus dem Windraum unterhalb des Rostes durch den freigelegten Spalt in den Feuerraum hinein. Ein Abstellen des Windes während des Abschlackens ist also nicht erforderlich.

Die Anordnung einer zweiten Abschlußplatte am vorderen Schlackenrostende ermöglicht es, den Windraum unterhalb des Schlackenrostes vom Hauptwindraum unterhalb des Brennrostes zu trennen. Beide Windräume können also unter verschiedenen Druck gesetzt werden. Ist beispielsweise der Schlackenrost aus irgend einem Grunde zu stark bedeckt, so kann man, um einen schnellen, guten Ausbrand zu erzielen, den Luftdruck unterhalb des Schlackenrostes verstärken, ohne gleichzeitig den Druck unterhalb des Brennrostes steigern zu müssen. Umgekehrt kann man bei schwach bedecktem Schlackenrost, beispielsweise unmittelbar nach dem Abschlacken, den Winddruck unterhalb des Schlackenrostes vermindern oder ganz abstellen, um hierdurch unwirtschaftlichen Luftüberschuß zu vermeiden. Es ergibt sich also durch die Anordnung der beiden Abschlußplatten eine sehr günstige Zonenreglung der Luftzufuhr getrennt für den Brennrost und Schlackenrost.

Die Abbildung zeigt ein Ausführungsbeispiel der Erfindung. Es bedeutet *r* den Hauptrost und *s* den Schlackenrost, an welchen hinten die Abschlußplatte *a* und vorn die Abschlußplatte *b* angelenkt ist. Wird der Schlackenrost *s* von Hand oder mechanisch durch die Zugstange *z* in der Pfeilrichtung nach links ausgefahren, so kommen die Abschlußplatten in die punktierte Lage *a'* und *b'*. In diesem Falle stürzt die sich vorher auf dem Schlackenrost *s* befindliche Schlacke nach dem Schlackenschacht *t* ab, wobei sie über die Abschlußplatte *a* abrutscht. Gleichzeitig verhindert diese Abschlußplatte *a* ein Überströmen von Wind aus dem Raum *h* unterhalb des Rostes *r* durch den vom Schlackenrost freigelegten Spalt in den Feuerraum *f*.

Die am vorderen Schlackenrostende angelenkte Platte *b* trennt den Hauptwindraum *h* unterhalb des Brennrostes *r* von dem Windraum unterhalb des Schlackenrostes *s*. Beide Windräume erhalten eine gesonderte Luftzufuhr, wobei der Winddruck in jeder Zone unabhängig voneinander durch Drosselorgane *d* bzw. *c* eingestellt werden kann.

PATENTANSPRÜCHE:

1. Ausfahrbarer Schlackenrost für mit Unterwind betriebene Feuerungen, dadurch gekennzeichnet, daß am hinteren Ende des Schlackenrostes eine über die ganze Rostbreite reichende, sich unten auf eine Querwand des Aschenfalles stützende Abschlußplatte (*a*) angelenkt ist, welche bei ausgefahrenem Schlackenrost verhindert, daß Luft aus dem Windraum (*h*) durch die Öffnung für den Schlackenrost unmittelbar in den Feuerraum tritt.

2. Ausfahrbarer Schlackenrost nach Anspruch 1 mit getrennten Windräumen unter dem Hauptrost und dem Schlackenrost, dadurch gekennzeichnet, daß auch am vorderen Ende des Schlackenrostes eine solche Abschlußplatte (*b*) angelenkt ist, welche den besonderen Windraum unterhalb des Schlackenrostes vom Hauptwindraum unterhalb des Hauptrostes abgrenzt.

J. A. Topf & Söhne in Erfurt

Düsenplattenrost

Patentiert im Deutschen Reiche vom 27. August 1931 ab

Die Erfindung bezieht sich auf einen Düsenplattenrost für feinkörnigen Brennstoff, bei dem die in gegenläufig bewegten Querreihen nebeneinanderliegenden Platten sich an den vorderen, der Brennstoffzufuhr zugekehrten Enden auf schwingende Querträger und an den anderen Enden auf die in der nächstfolgenden Reihe liegenden Platten stützen.

Bei derartigen Rosten müssen die Platten im kalten Zustand mit einem gewissen Spiel verlegt werden, damit sie sich bei der Erwärmung unbehindert ausdehnen können und Verklemmungen im Betriebe vermieden werden. Andererseits nötigt die Verwendung feinkörnigen Brennstoffes dazu, besondere Mittel vorzusehen, die einen Durchfall des Brennstoffes zwischen den einzelnen Platten verhüten.

Gemäß der Erfindung werden schalenförmige Auffangkörper vorgesehen, welche die Stoßfugen seitlich benachbarter Rostplatten nach unten abdecken, sich am vorderen Ende auf die für die zugeordneten Rostplatten vorgesehenen Querträger und am hinteren Ende, ebenso wie die Platten, auf die folgenden Platten stützen. Diese Auffangkörper werden durch seitliche Zapfen mitgenommen, welche in Ausschnitte hineinragen, die durch nach unten vorspringende, den Querträger umfassende Lappen der Platten gebildet werden.

Bei Rosten mit über die ganze Rostlänge durchlaufenden Roststäben ist es an sich bereits vorgeschlagen worden, unter den im wesentlichen T-förmig ausgebildeten eigentlichen Roststäben Auffangkörper derart anzuordnen, daß zwischen Roststäben und Auffangkörpern Spalte zum Durchtritt der Verbrennungsluft belassen wurden, wobei ein Rostdurchfall verhindert wird. Von diesen bekannten Auffangkörpern wird in Anwendung auf Düsenplattenroste Gebrauch gemacht, bei denen die Platten in gegenläufig bewegten Querreihen nebeneinanderliegend angeordnet sind.

Die Erfindung ist durch die Zeichnungen in schematischer Weise dargestellt, und zwar ist

Abb. 1 ein Längsschnitt durch den Rost,

Abb. 2 ein Querschnitt nach Linie *A-B* in Fig. 1,

Abb. 3 ein in größerem Maßstab gehaltener Querschnitt durch die benachbarten vorderen Enden zweier Düsenplatten und einen der Stoßstelle zugeordneten Auffangkörper.

Der Düsenplattenrost besitzt Reihen von aufeinanderfolgenden Platten *a*, *b*, *c*, die sich mit den nach der Brennstoffzuführung zugekehrten Enden auf um Querwellen *d* schwingende Querträger *e* stützen, mit den anderen nasenförmigen Enden *n* aber sich auf die Rücken der nächstfolgenden Plattenreihe auflegen. Jede einzelne Plattenreihe *a*, *b*, *c* besteht aus einer Vielzahl von nebeneinanderliegenden Platten a^1, a^2, a^3 ... Die einzelnen Rostrahmen sind in nicht Gegenstand der Erfindung bildender Weise an gegenläufig bewegte Stangen derartig angeschlossen, daß bei einer Vorwärtsbewegung der Plattenreihen *a*, *c* usw. die dazwischen angeordneten

Document 157: Patent J.A. Topf & Söhne in Erfurt, No. 576135. "Plate-grate with nozzles." 20. April 1933. Source: Deutsches Patentamt.

576 135

Plattenreihen *b* usw. eine Rückwärtsbewegung ausführen, und umgekehrt.

Um den Platten die Möglichkeit einer Wärmeausdehnung ohne Gefahr von Verklemmung zu geben, sind sie im kalten Zustand in der aus Abb. 3 für die Platten a^1, a^6 ersichtlichen Weise mit einem gewissen Spiel *s* verlegt. Um einen dauernden Brennstoffverlust durch den Spalt *s* zu verhüten, sind unter der Stoßfuge schalenförmige Auffangkörper *f* von U-förmigem Querschnitt gelegt, die sich mit ihrer Unterseite am vorderen Ende auf die Querträger auflegen, auf denen auch die zugehörigen Platten aufruhen, während die hinteren Enden, ebenso wie die Rostplatten, auf dem Rücken der folgenden Plattenreihe aufliegen. Die Auffangkörper besitzen seitliche Zapfen *z*, die in Ausschnitte hineinragen, welche durch nach unten vorspringende Lappen *l* der Rostplatten gebildet sind, mit denen diese den Querträger umfassen, wodurch sie mitgenommen werden.

PATENTANSPRUCH:

Düsenplattenrost für feinkörnigen Brennstoff, bei dem die in gegenläufig bewegten Querreihen nebeneinanderliegenden Platten sich an den vorderen, der Brennstoffzufuhr zugekehrten Enden auf schwingende Querträger und an den anderen Enden auf die in der nächstfolgenden Reihe liegenden Platten stützen, dadurch gekennzeichnet, daß schalenförmige Auffangkörper (*f*), die in an sich bekannter Weise die Stoßfugen (*s*) seitlich benachbarter Rostplatten nach unten abdecken, am vorderen Ende sich auf die Querträger (*e*) für die zugeordneten Platten, am hinteren Ende ebenso wie diese auf die folgenden Platten stützen, wobei sie durch seitliche Zapfen (*z*), welche in durch nach unten vorspringende, den Querträger umfassende Lappen (*l*) gebildete Ausschnitte hineinragen, mitgenommen werden.

J. A. Topf & Söhne in Erfurt

Verfahren und Ofen zur Zurückgewinnung von Blei und Kupferdraht aus Kabeln

Patentiert im Deutschen Reiche vom 29. September 1932 ab

In Betrieben, in welchen alte Kabel und Kabelreste anfallen und sich ansammeln, macht sich neuerdings das Bestreben geltend, diese Reste und alten Kabel abzubrennen, um die Metalle zurückzugewinnen.

Bisher wurden zu diesem Zweck offene Feuerstellen errichtet, über welche ein Blech gelegt wurde. Auf diesem wurden die Kabel stückweise aufgeschichtet und infolge der Erhitzung von unten her zunächst abgebrannt und dann in flüssiges Blei und Kupferdraht zerlegt. Das Blei floß in einen danebenstehenden Bleikessel, der noch besonders beheizt wurde. Durch die hierbei frei werdenden Bleidämpfe wurden die Bedienungsmannschaften vielfach gesundheitlich schwer geschädigt. Die gewonnenen Kupferdrähte waren teilweise noch stark mit Bleikrätze behaftet, auch kam das Blei unsauber in den Bleikessel. Der Gewinn an Metall war ungenügend.

Nach der Erfindung soll die Zurückgewinnung der Metalle durch unmittelbares Abbrennen der Kabel in einem geschlossenen Ofen ohne besondere Feuerung erfolgen. Hierzu wird der Ofen der nachstehend beschriebenen Bauart verwendet.

Eine Ausführungsform des Ofens ist in Fig. 1 im Längsschnitt und in Fig. 3 im Horizontalschnitt dargestellt. Fig. 2 zeigt eine Abbrennplatte im Querschnitt.

In den Ofen sind schräg liegende Abbrennplatten *a* eingebaut, auf welchen die durch die Aufgabeöffnung *i* eingeführten Kabel durch Abfallwachsdraht in Brand gesetzt werden. Dadurch werden gleichzeitig die Schamottewandungen *b* und auch die Abbrennplatten *a* selbst so weit erwärmt, daß die Bestandteile aus Papier und Jute verbrennen. Bei der Verbrennung dieser Bestandteile wird so viel Wärme entwickelt, daß der Bleimantel der Kabel schmilzt und der Kupferdraht frei wird. Das geschmolzene Blei läuft von den geneigt angeordneten Abbrennplatten *a* in eine dahinterliegende Bleirinne *c*, deren Auslauf nach außen hin ebenfalls schräg gelagert ist. Unter dem Rinnenauslauf ist ein von den Abgasen beheizter außen angebauter Bleikessel *d* angeordnet (Fig. 3), in welchem das flüssige Blei gesammelt wird. Innerhalb des Ofens ist eine Abdeckplatte *k* über der Bleirinne *c* vorgesehen, damit beim Herausziehen des Kupferdrahtes nicht Schmutz in die Rinne gelangt und dauernd freier Ablauf für das Blei gewahrt bleibt.

Die in der Mitte vertieften oder als flache Rinnen ausgebildeten Abbrennplatten *a* haben seitliche Abweiser *q*, wodurch das fließende Blei in die Mitte der Brennbahn geführt (Fig. 2) und somit das seitliche Schamottemauerwerk nicht beschädigt wird.

Der von Blei und Jute befreite Kupferdraht wird über die Abbrennplattenbahn *a* nach unten auf einen innerhalb des Ofens angeordneten Abklopfrost *g* gezogen, hier von dem noch anhaftenden Blei und sonstigen Rückständen befreit und dann durch die der Aufgabeöffnung gegenüberliegenden Entnahme-

Document 158: Patent J.A. Topf & Söhne in Erfurt, No. 587149. "Process and furnace for the recovery of lead and pieces of wires from cables." 12 October 1933. Source: Deutsches Patentamt.

587 149

öffnung *k* mittels eines Schürhakens aus dem Ofen entfernt.

In der Zwischenzeit werden frische Kabel durch die Aufgabe *i* weiter zugelegt, so daß der Ofen dauernd auf Temperatur und somit in Betrieb gehalten wird. Durch die Aufeinanderfolge der Teile *a*, *c* und *g* und das Gegenüberliegen der Öffnungen *i*, *k* wird ein ununterbrochener Betrieb sowie ein gutes und geschütztes Bedienen des Ofens ermöglicht. Die gebildeten Abgase steigen von den Abbrennplatten *a* nach oben in einen seitwärts angeordneten Kanal *m*, werden in diesem schräg nach unten gezogen, gehen um eine Sperrmauer *n* herum unter die Bleirinne *c*, streichen um den Bleikessel *d* herum, um das Blei flüssig zu halten und gelangen dann unter den Aschensack *p* zum Schornstein *o*. Durch diesen langen Weg werden die Abgase voll und wärmewirtschaftlich ausgenutzt.

PATENTANSPRÜCHE:

1. Verfahren zur Rückgewinnung von Blei und Kupferdraht aus Kabeln, dadurch gekennzeichnet, daß die organische Substanz der Kabel in einem nicht beheizten geschlossenen Ofen abgebrannt und das abgeschmolzene Blei und der entbleite Kupferdraht getrennt aus dem Ofen entfernt werden.

2. Ofen zur Ausführung des Verfahrens nach Anspruch 1, dadurch gekennzeichnet, daß hinter einer Aufgabeöffnung (*i*) für die Kabel geneigt liegende Abbrennplatten (*a*) angeordnet sind, auf welchen die Kabel unmittelbar entzündet werden und an welche hintereinander eine mit Überdekkung (*k*) versehene Bleisammelrinne (*c*), die in einen außen befindlichen Bleikessel (*d*) mündet, und eine der Aufgabeöffnung (*i*) gegenüberliegende Entnahmeöffnung (*k*) für den Kupferdraht anschließen.

3. Ofen nach Anspruch 2, dadurch gekennzeichnet, daß die Abbrennplatten (*a*) in der Mitte vertieft oder als flache Rinnen ausgebildet sind.

4. Ofen nach Anspruch 2, dadurch gekennzeichnet, daß die Abbrennplatten (*a*) mit seitlichen Abweisern (*q*) zum Schutze des Mauerwerkes gegen korrodierende Wirkung des Bleies versehen sind.

5. Ofen nach Anspruch 2, dadurch gekennzeichnet, daß zwischen Bleisammelrinne (*c*) und Entnahmeöffnung (*k*) ein Abklopfrost (*g*) zur Reinigung des Kupferdrahtes innerhalb des Ofens angeordnet ist.

6. Verfahren zum Betriebe des Ofens nach Anspruch 2, dadurch gekennzeichnet, daß der Bleikessel (*d*) von den Abgasen des Ofens beheizt wird.

Beschreibung.

Luftgekühlte Rostplatten für mechanische Vorschubroste.

In jeder Feuerung ist meist der Rostbelag dem größten Verschleiß unterworfen. Je nach der Brennstoffsorte und den dadurch bedingten Verbrennungs-Temperaturen ist die Lebensdauer des Rostbelages verschieden, gleichzeitig spielt auch die Bauart des Rostes eine wesentliche Rolle. Gut bediente Roste aus Roststäben besitzen meist eine verhältnismäßig lange Lebensdauer, wenn die Verbrennungsluft durch Kühlrippen so zweckmäßig geführt wird, daß eine gleichmäßig gute Kühlung der Roststäbe über die durch diese gebildete Gesamtrostfläche gewährleistet ist. Dabei ist es gleichgültig, ob die Verbrennungsluft durch natürlichen oder künstlichen Zug angesaugt oder auch als Unterwind - also mit Pressung - zugeführt wird.

Werden dagegen die Roste aus mit Düsen für den Luftdurchtritt versehenen Rostplatten hergestellt - was bei mechanischen Vorschubrosten überwiegend der Fall ist -, so wird eine gleichmäßig gute Kühlung der Gesamtrostfläche in Frage gestellt, weil die bei diesen Rosten stets als Unterwind mit Pressung zugeführte Verbrennungsluft infolge der stufenförmigen Anordnung und der bisher allgemein üblichen Ausbildung der Rostplattenkörper kaum mit deren Köpfen in Berührung kommt. Infolgedessen werden naturgemäß die Köpfe der Rostplatten, die ja außerdem den höchsten Temperaturen ausgesetzt sind, stets zuerst zerstört. Wegen des dadurch bedingten stärkeren Materialverbrauch und den laufenden hohen Instandsetzungskosten waren daher mechanische Vorschubroste für die Verbrennung von hochwertigen Brennstoffen bisher nicht geeignet.

Die Rostplattenkörper müssen also so ausgebildet sein, daß in jeder Stellung dieser auch deren Köpfe von der Verbrennungsluft zwangsläufig kühlend bespült werden, bevor diese Luft durch vorgesehene Düsen in den Feuerraum tritt. Die Erfindung gewährleistet durch besondere Ausbildung der Rostplattenkörper und

EMPFÄNGER

Reichsamtsamt, Berlin SW 61

002702

dadurch bewirkte zwangsläufige Führung der Verbrennungsluft eine gl ichmäßig gute Kühlung der Gesamtrostfläche - insbesondere auch der Rostplatten-Köpfe - auch bei mechanischen Vorschubrosten. Da außerdem je nach Bedarf außer der Verbrennungsluft noch Zusatz-Kühlluft zur nachhaltigeren Kühlung des Rostbelages zugeführt werden kann, ist es möglich, Vorschubroste auch mit hochwertigen Brennstoffen zu betreiben.

Um Zusatz-Kühlluft zur nachhaltigeren Kühlung des Gesamtrostbelages anwenden zu können, ist ferner in an sich bekannter Weise eine Unterteilung des Raumes unter diesem in einzelne Zonen vorgesehen, die sich außerdem für eine wirtschaftliche Feuerführung vorteilhaft auswirkt.

In der Zeichnung zeigt Abb. 1 einen Querschnitt durch einen luftgekühlten Vorschubrost mit Zonenunterteilung und abwechselnd feststehenden und beweglichen Rostbelagreihen. Während Abb.2 die Rostplatte einer feststehenden Rostbelagreihe in der Draufsicht wiedergibt, stellt Abb. 3 einen Schnitt quer durch diese Rostplatte und Abb. 4 einen Schnitt parallel zur Rostplattenoberfläche dar. Abb. 5 zeigt den gleichen Schnitt durch die Rostplatte einer beweglichen Rostbelagereihe.

Gemäß Abb. 1 besteht jede Zone aus einem Luftsammelkasten a mit durchgehenden zweiteiligen Einbauten b und c. Über jedem Luftsammelkasten a befindet sich je eine bewegliche Rostplattenreihe d und eine desgleichen feststehende e. Vom Gebläse aus tritt die Luft durch die Öffnung f in den oberen Teil b der Einbauten des Luftsammelkastens a und von dort in den Raum unter dem Rostbelag. Hier teilt sich die Luftmenge, und zwar tritt ein Teil durch die Öffnungen g (Abb.4) der feststehenden Rostplattenreihe e und der andere Teil durch die Öffnungen h (Abb.5) der beweglichen Rostplattenreihe d in den Rostbelag selbst ein. Aus den Abbildungen 4 und 5 ist der weitere Weg dieser Luftteilmengen ersichtlich, der in beiden Fällen die Luft zwangsläufig über die Fläche jedes Rostplattenkörpers und insbesondere an den

- 3 -

EMPFÄNGER

Reichspatentamt, Berlin SW 61.

0.02703

Köpfen der Rostplattenreihen kühlend vorbeiführt. Bei den feststehenden Rostplattenreihen e tritt die Luft durch die Öffnungen i und bei den beweglichen Rostplattenreihen d durch die Öffnungen k wieder aus den Kanälen der Rostplatten aus, abzüglich der Luftmengen, welche als Verbrennungsluft durch die Luftdüsen l - Abbildungen 2 und 3 - in den Feuerraum tritt. Die Anordnung der Luftdüsen l erfolgt zweckmäßig in den Luftabführenden Kanälen, also hinter der an den Rostplatten-Köpfen befindlichen Umlenkung, da so etwaiger Rostdurchfall leicht durch die Zusatz-Kühlluft ausgetragen wird. Nach Verlassen des Rostbelages wird die Zusatz-Kühlluft in dem unteren Teil e der Einbauten des Luftsammelkastens a gesammelt, von wo sie dann durch die an dessen Ende befindliche Öffnung m ins Freie treten oder - da sie vorgewärmt ist - durch das Gebläse rückgesaugt und vom Neuen verwendet werden kann. Etwa mitgerissener Rostdurchfall wird im Raum n des Luftsammelkastens a ausgeschieden und durch Ascheabnahme-Vorrichtungen o von dort abgesogen, ohne daß an dieser Stelle Luft austreten kann.

Um für jede Zone die Verbrennungsluftmenge einstellen zu können, wird an der Austrittsöffnung m im unteren Teil e der Einbauten des Luftsammelkastens a eine (nicht gezeichnete) Drosselklappe angeordnet. Wird diese Klappe z.B. ganz geöffnet, so dient die gesamte Luftmenge nur zur Kühlung des Rostbelages, weil die Öffnungen m dem Luftdurchtritt weniger Widerstand entgegensetzen, als die Luftaustritts-Düsen l des Rostbelages. Ist die Klappe dagegen nahezu geschlossen, so ist fast die gesamte Luftmenge gezwungen, durch die Düsen l zu treten und damit der Verbrennung zu dienen. Diese Einstellmöglichkeit gestattet, für jede Zone das Verhältnis zwischen Zusatz-Kühlluftmenge und Verbrennungsluftmenge festzulegen. Dabei muß jedoch mit Rücksicht auf den Rostdurchfall stets so viel Zusatz-Kühlluft austreten, daß sich die Kanäle der Rostplatten nicht mit Asche oder Kohleteilchen zusetzen können.

Die durch Anwendung der Erfindung nachgewiesene Möglichkeit, mechanische Vorschubroste auch mit hochwertigen Brennstoffen

- 4 -

Document 159: continued.

J.A.TOPF & SÖHNE ERFURT

TAG 16.11.42 BLATT 4

ANGEB

Reichspatentamt, Berlin NW 61

0027[illegible]

zu betreiben, hat in der Jetztzeit besondere Bedeutung. In dem Zeitem der Belieferung mit gleichbleibenden Brennstoffen, herrschte das Bestreben vor, Leistung und Wirkungsgrad einer Feuerung bei Verwendung einer bestimmten Kohlensorte zu steigern. Heute gilt es dagegen, die Brennstoff-Grundlage einer Feuerung so zu verbreitern, daß der Feuerungsbetrieb auch mit ursprünglich nicht vorgesehenem Brennstoffen durchgeführt werden kann und dabei doch noch gute Wirkungsgrade zu erreichen sind. Die Erfindung gestattet, Vorschub-Feuerungen nach jeder Richtung hin mit einem großen Spielraum in Bezug auf den Brennstoff zu betreiben und gewährleistet dabei durch die Verwendung des beschriebenen Rostbelages in Verbindung mit der Zonenaufteilung einen Feuerungsbetrieb mit hochprozentigem Wirkungsgrad. Voraussetzung ist natürlich, daß sich ein Brennstoff überhaupt zur Verbrennung auf einem mechanischen Vorschubrost eignet.

Verfahren und Vorrichtung zur Verbrennung von Leichen, Kadavern und Teilen davon

Patentiert im Gebiet der Bundesrepublik Deutschland vom 24. Juni 1950 an
Patentanmeldung bekanntgemacht am 31. Oktober 1951
Patenterteilung bekanntgemacht am 13. November 1952

Die Erfindung betrifft ein Verfahren zur Verbrennung von Leichen, Kadavern und Teilen davon durch rekuperativ erhitzte Verbrennungsluft und eine Vorrichtung zur Durchführung des Verfahrens.

Fast alle bisher bekanntgewordenen Einäscherungsverfahren verwenden im Rekuperativverfahren erhitzte Luft als Verbrennungsluft für die Verbrennung der Leichen. In der gleichen Weise wie bei allen Verbrennungsvorgängen in der Wärmetechnik soll der Verbrennungsprozeß durch die Vorwärmung der Luft thermisch auf eine höhere Stufe gehoben und damit die Verbrennungstemperatur gesteigert werden.

Der Heizwert einer Leiche bzw. ihr Brennwert wurde bisher grundsätzlich nach dem Fettgehalt der Leiche beurteilt. Die im Fettkörper der menschlichen Leiche enthaltenen CH (Kohlewasserstoff)-Verbindungen (Fette) weisen zum Teil eine sehr niedrige Zündtemperatur auf und verbrennen bei höchsten Temperaturen. Dagegen ist es bisher nicht gelungen, die im Eiweißkörper in Verbindung mit N (Stickstoff) enthaltenen CH-Verbindungen bei Fehlen von reinen Fettkörpern und damit reinen CH-Verbindungen exotherm zu verbrennen. Der Eiweißkörper setzt mit seinem relativ hohen N-Gehalt (etwa 25 %) seiner Verbrennung heftigsten Widerstand entgegen. Seine Zündtemperatur liegt bei etwa 800° C.

Bei bisher erreichten Lufttemperaturen von 400 bis 500° C konnte somit die im Eiweißkörper enthaltene Stickstoffkomponente in ihrer die Verbrennung hemmenden Wirkung nicht aufgehoben werden.

Erfahrungsgemäß vermag erst die Einwirkung von Luft von 800 bis 900° die Trennung des N von den

Document 160: Patent J.A. Topf & Söhne, Wiesbaden, No. 861731. "Process and device for the combustion of corpses, carrion, or parts thereof." 24 June 1950. Source: Deutsches Patentamt.

2 861 731

CH-Verbindungen zu vollziehen, trotzdem es sich auch im Eiweißkörper nicht um eine chemische Verbindung von N + CH handelt, sondern nur um eine jener lockeren Verbindungen von N, wie sie dieser, als sehr träge bekanntes Gas, vielfach eingeht. Daß bei der Ausschaltung des N auch eine gewisse Wärmemenge verbraucht wird, ist anzunehmen. Jedoch wird aber niemals der große Wärmeverbrauch auftreten, der notwendig ist, um N aus einer festen chemischen Verbindung frei zu machen. Es werden auch bei der Verbrennung der CH-Verbindungen im Eiweißkörper nahezu die Wärmemengen frei, welche bei der Verbrennung von reinen CH-Verbindungen ihrer Zusammensetzung entsprechend entbunden werden.

Für eine menschliche Leiche von etwa 70 kg Gewicht, einem Gehalt von etwa 12 kg C, etwa 2 kg H_2 und etwa 0,5 kg P, bei etwa 55,5 kg H_2O + N errechnet sich ein Mindestheizwert von etwa 160 000 WE, wozu noch die Sargverbrennungswärme zu rechnen ist.

Das endgültige Ziel in der Kremation mußte demnach sein, die jeweilige notwendige Verbrennungsluftmenge ohne zusätzliche Wärmezufuhr, lediglich unter Ausnutzung der Abgase auf 800 bis 900° zu erhitzen, um die im Eiweißkörper enthaltenen beträchtlichen, aber an N gebundenen CH-Mengen restlos zu verbrennen und durch Freiwerdung dieser Wärmemengen die Verbrennung jeder menschlichen Leiche ohne zusätzliche Wärmezufuhr zu ermöglichen.

Mittels des Einäscherungsverfahrens gemäß der Erfindung ist dieses Ziel erreicht. Es werden nicht nur die notwendigen Wärmemengen für die Verdampfung und den Abtransport des Wassers in der Leiche verfügbar, sondern auch diejenigen für das Verbrennen und Veraschen der Leiche selbst. Abzüglich der Wärmemengen, die im Abgas verlorengehen, verbleiben noch immer bedeutende Wärmemengen disponibel für das Hochheizen des Ofens bzw. die Erhaltung seines Beharrungszustandes.

Ein eingangs erwähntes Verfahren wird gemäß der Erfindung derart durchgeführt, daß die Leiche mit dem Sarg in einer Muffel auf einem Balkenrost so lange der Einwirkung eines unter Aufwand von Brennstoff rekuperativ beheizten Luftstromes und/oder der Strahlungseinwirkung erhitzter Muffelwände ausgesetzt wird, bis der in Brand geratene Sarg und die durch die Verdampfung ihres Wassergehaltes brennfähig gewordene Leiche zerfällt, und daß die Teile auf einem darunter befindlichen kleinen Ausbrennrost mit der auf 800 bis 900° C rekuperativ, hauptsächlich durch die Verbrennungswärme der Leichenteile erhitzten erforderlichen Verbrennungsluftmenge exotherm verbrennen, wobei die sich bildenden Verbrennungsgase von oben nach unten durch den Ausbrennrost abströmen und sich zwecks vollständiger Verbrennung der flüchtigen Bestandteile mit unter dem Ausbrennrost zugeführter heißer Verbrennungsluft mischen, und daß die Verbrennungsgase unmittelbar in den Rekuperator geleitet werden, in welchem sie ihren Wärmeinhalt an die Verbrennungsluft abgeben, so daß die Verbrennung ohne weiteren Aufwand an Brennstoff unterhalten wird.

Die Abbildung zeigt einen Ofen zur Durchführung des Verfahrens.

Die den Sarggrößen angepaßte und in den Normalmaßen ausgeführte Muffel *A* ist als Verbrennungsraum nur so lange wärmewirtschaftlich wirksam, wie der Muffelraum von den Verbrennungsgasen voll ausgefüllt wird. Der bisherige ausschließlich in der Muffel durchgeführte Verbrennungsprozeß muß Trocknungsprozeß werden und als solcher beendet sein, sobald nach Verbrennen des Sarges und Abfallen des Kopfes und der Gliedmaßen die nur aus zwei Steinen bestehende Rostanlage die Teile des Rumpfes selbsttätig in den kleinen über der Drehplatte liegenden eigentlichen Verbrennungsraum *B* durchfallen läßt. Dauer dieses Prozesses in der Muffel 20 bis 30 Minuten.

In diesem kleinen Verbrennungsraum kommt die auf 800 bis 900° C erhitzte Luft innig mit den noch unverbrannten Eiweißstoffen in Berührung, trennt N von den CH-Verbindungen und bringt CH bei Temperaturen bis über 1200° C restlos zur Verbrennung. Dieser eigentliche Verbrennungsprozeß dauert 10 bis 15 Minuten. Die Drehplatte kann gedreht werden, und die gesamten Aschereste fallen zum Nachglühen in den dritten Verbrennungsraum auf den Ascherost *C*.

Die notwendige Verbrennungsluft wird in einem aus Schamottesteinen gemauerten oder metallischen Lufterhitzer *D* auf 800 bis 900° C erhitzt. Beim Anfahren des Ofens liefert ein Heißluftgasbrenner *E* Verbrennungsgase von 1200 bis 1300° C für das Hochheizen des Lufterhitzers. Die Heißluft wird regelbar in die Muffel, über der Drehplatte und unter dem Ascherost zugeführt. Auch der Heißluftgasbrenner wird vom Lufterhitzer mit Luft von max. 600° C beliefert.

Sobald der Ofen Beharrungszustand erreicht hat, wird der Gasbrenner abgestellt, und die Beheizung des Lufterhitzers erfolgt nur durch die gleichfalls sehr heißen Abgase insbesondere während der eigentlichen Verbrennungsphase auf der Drehplatte, bei der die Eiweißkörper lebhaft verbrennen.

Die gesamte Einäscherungsdauer wird durch das neue Einäscherungsverfahren bis 45, oft bis 30 Minuten reduziert.

Die Qualität der Asche kennzeichnet diese als vollkommen verbrannt, keimfrei und von so mäßigem Volumen, daß die normale Urne selten ganz gefüllt wird.

PATENTANSPRÜCHE:

1. Verfahren zur Verbrennung von Leichen, Kadavern und Teilen davon durch rekuperativ erhitzte Verbrennungsluft, dadurch gekennzeichnet, daß die Leiche mit dem Sarg in einer Muffel auf einem Balkenrost so lange der Einwirkung eines unter Aufwand von Brennstoff rekuperativ beheizten Luftstromes und/oder der Strahlungseinwirkung erhitzter Muffelwände ausgesetzt wird, bis der in Brand geratene Sarg und die durch die Verdampfung ihres Wassergehaltes brennfähig gewordene Leiche zerfällt, und daß die Teile auf einem darunter befindlichen kleinen Ausbrennrost mit der auf 800 bis 900° C rekuperativ, haupt-

Document 160: continued.

sächlich durch die Verbrennungswärme der Leichenteile, erhitzten erforderlichen Verbrennungsluftmenge exotherm verbrennen, wobei die sich bildenden Verbrennungsgase von oben nach unten durch den Ausbrennrost abströmen und sich zwecks vollständiger Verbrennung der flüchtigen Bestandteile mit unter dem Ausbrennrost zugeführter heißer Verbrennungsluft mischen, und daß die Verbrennungsgase unmittelbar in den Rekuperator geleitet werden, in welchem sie ihren Wärmeinhalt an die Verbrennungsluft abgeben, so daß die Verbrennung ohne weiteren Aufwand an Brennstoff unterhalten wird.

2. Ofen zur Verbrennung von Leichen, Kadavern und Teilen davon mit rekuperativ erhitzter Verbrennungsluft mit unter dem Balkenrost einer Muffel befindlichen abklapp- oder einfahrbarem Ausbrennrost zur Durchführung des Verfahrens nach Anspruch 1, dadurch gekennzeichnet, daß der Balkenrost nur aus zwei Balken besteht und über einen Trichterboden angeordnet ist, dessen Böschungsflächen zur Beförderung der Sarg- und Leichenteile auf den aufklapp- oder einfahrbaren Ausbrennrost dienen und daß über dem Ausbrennrost Zuführungsöffnungen für die Erstluft und in dem Raum unterhalb des Ausbrennrostes der Verbrennungsgasabzug in den Rekuperator, ein Heißluftgasbrenner zur zeitweisen Beheizung des Rekuperators und Öffnungen zur Zuführung von Zweitluft angeordnet sind und sein Boden einen ebenfalls abklappbaren, entsprechend der fortgeschrittenen Verbrennung kleineren Ausglührost bildet, zu dem ebenfalls Heißluftzuführungsöffnungen führen.

3. Ofen nach Anspruch 2, dadurch gekennzeichnet, daß der Feuerraum mit einer verhältnismäßig dünnen Auskleidung von geringer Wärmekapazität ausgestattet ist und von einer starken Isolierschicht umgeben ist.

Städt. Krankenhaus in Erfurt

VOLKSGESUNDHEIT UND HYGIENE

sind der Ausgangspunkt für die überaus sorgfältige Behandlung der Spezialfragen, die unsere **Abteilung Ofenbau** seit Jahrzehnten bearbeitet. Unsere Spezialöfen dienen demnach dem Ziel, der Verbreitung von Krankheiten wirksam zu begegnen.

Vorbeugen ist besser . . .

Die technisch-wissenschaftlichen Erkenntnisse und umfassenden praktischen Erfahrungen haben es uns ermöglicht, eine restlose Vernichtung der Krankheitskeime in den Krankenabfällen, Mull und ähnlichen Stoffen durch die reinigende Kraft des Feuers zu erreichen.

TOPF-OFENBAU

Hierbei kamen uns zugute unsere 60jährigen Erfahrungen auf dem Gebiete des Feuerungsbaues und der Wärmewirtschaft. Die Güte unserer Spezialkonstruktionen zeigt sich an der geruchlosen, rauchschwachen Verbrennung und an der weitgehenden Ausnutzung des Brennstoffs, d. h. an der wärmewirtschaftlich einwandfreien Arbeitsmethode, die sich im Betrieb dieser Ofenanlagen auswirkt.

TOPF-Abfallvernichtungsöfen – für Gas-, Kohle-, Öl- oder Elektrobeheizung – arbeiten demnach nicht nur hygienisch einwandfrei, sondern überaus wirtschaftlich.

Krankenhaus-Abfallvernichtung

Immer mehr gehen die Krankenhäuser, Kliniken und auch Privatsanatorien dazu über, **Spezialofenanlagen zur Vernichtung von Krankenabfällen**, Verbandsresten, Amputationsteilen anzuwenden. (Der Dampfkessel der Heizungsanlage ist hierfür nicht geeignet.) Die Öfen beanspruchen nur wenig Platz und eine geringe Wartung; sie eignen sich somit ebenso für die kleineren wie auch für die großen Anstalten.

Document 161: continued.

INDUSTRIELLE ABFALLWIRTSCHAFT

Die Anwendung von Spezialofenanlagen für die Abfallvernichtung in großen Industriewerken ist im Laufe des letzten Jahrzehnts im starken Fortschreiten; erfordert doch die Lagerung z. B. von anfallendem Müll viel Platz und wirkt sich in unhygienischer Weise aus. Die Abfuhr des Gutes kostet Arbeitskraft, Zeit und Geld. Die Verbrennung des Mülls hilft also sparen und stellt die Möglichkeit dar, die dabei anfallende Abgaswärme zur Warmwasserbereitung oder Raumheizung auszunutzen.

Erhaltung der Werte

Der Vierjahresplan hat uns gelehrt, die Erfassung auch kleinster Mengen wertvollen Rohstoffes vorzusehen. Es geht deshalb nicht nur um die Vernichtung des Abfalls, sondern auch um die Erhaltung der in diesen Abfällen vorkommenden Werte, die zusammengenommen für die Volkswirtschaft von Bedeutung sind.

Über die industrielle Bedeutung dieser Abfallvernichtung innerhalb der Betriebe hinaus – hat die Abfallverwertung für Staatsbetriebe, Versorgungsbetriebe und Gemeindeverwaltungen eine ständig wachsende Bedeutung erlangt. Aus diesen Erfordernissen sind unsere Spezialkonstruktionen entstanden, die eine überaus vielseitige Anwendung erfahren • Einige dieser Ofentypen:

1. Der Kabel-Abbrennofen

erzielt eine restlose Rückgewinnung der wertvollen Metalle. Der Abbrennofen ist so konstruiert, daß er dabei gleichzeitig Kupfer und Blei trennt.

2. Der Müll-Verbrennungsofen

findet bei Gemeindeverwaltungen Anwendung. (Die Asche ergibt ein gutes Düngemittel.)

3. Der Kranz-Verbrennungsofen

ist ein wertvoller Helfer für Friedhofsverwaltungen. Die großen Mengen Kränze, die im Laufe eines Jahres anfallen und deren Lagerung Schwierigkeiten macht, werden schnell beseitigt. Die Asche kann ebenfalls zur Düngung verwendet werden. Das Metall der Bindedrähte wird zurückgewonnen.

4. Der Matratzen-Verbrennungsofen

ermöglicht sparsame und hygienische Vernichtung bei gleichzeitigem Rückgewinnen der in der Matratze enthaltenen Metalle.

Document 161: continued.

VIER TOPF-OFENTYPEN

Der Abfall-Vernichtungsofen AV 1

Abb. 1

ist leicht unterzubringen. Er eignet sich daher besonders für wissenschaftliche Institute, kleinere Krankenhäuser, Sanatorien, Kliniken und Entbindungsanstalten. Er vernichtet äußerst rauch- und geruchschwach Amputationsteile, Versuchstiere und Krankenabfälle • Dieser Ofen ist ähnlich dem Sputum-Vernichtungsofen mit Schmiedeeisen ummantelt. Er ist mit Schamottesteinen ausgemauert und mit Kieselgur isoliert • Der Aufgabekasten A hat einen seitlich aufgehenden isolierten Türverschluß. Unter dem Kasten ist die Feuerung C mit Aschefall D. Der Verbrennungsraum B erhält an der Rückwand als Abschluß eine Schamotte-Gitterwand, hinter dem der Abgaskanal E angeordnet ist. Der Rauchkanalschieber F schließt ihn außerhalb der Ofen-Ummantelung vom Schornstein ab und regelt die Zugstärke.

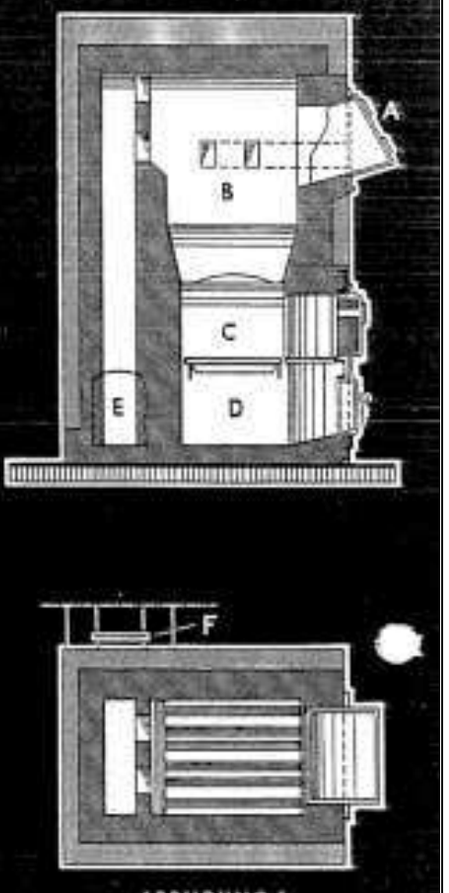

ABBILDUNG 1

Der Abfall-Vernichtungsofen AV 2

Abb. 2

Leichte Bedienung, schnellste Vernichtung der Abfälle bei geringem Brennstoffverbrauch, rauch- und geruchschwaches Arbeiten. Für mittlere Krankenhäuser, Kliniken, Hotels und dergleichen sehr geeignet • Diese Type besteht aus einem Ziegelsteingehäuse, das die Schamottemauerung und die Isolierung fest umschließt • Der Aufgabekasten A kann entweder oben auf dem Ofen angebracht werden, oder er tritt an die Stelle der Verschlußtür V (Type AV 3). Unter dem Verbrennungsraum B liegt der von der Feuerung C aus beheizte Schamotterost B 1. Dieser Rost nimmt nasse und andere schwer brennbare Abfälle auf. Mittels des Drehrostes D lassen sich die Aschereste leicht in den Ascheraum E befördern. Der Abgaskanal mit dem Fuchs F ist hinter einem Schamotte-Gitterwerk G angebracht. Der Schieber H schließt den Kanal ab. In dem Abgaskanal können Lufterhitzer-Rohre zur Heißluft-Erzeugung oder Rohrschlangen für die Warmwasser-Bereitung eingebaut werden.

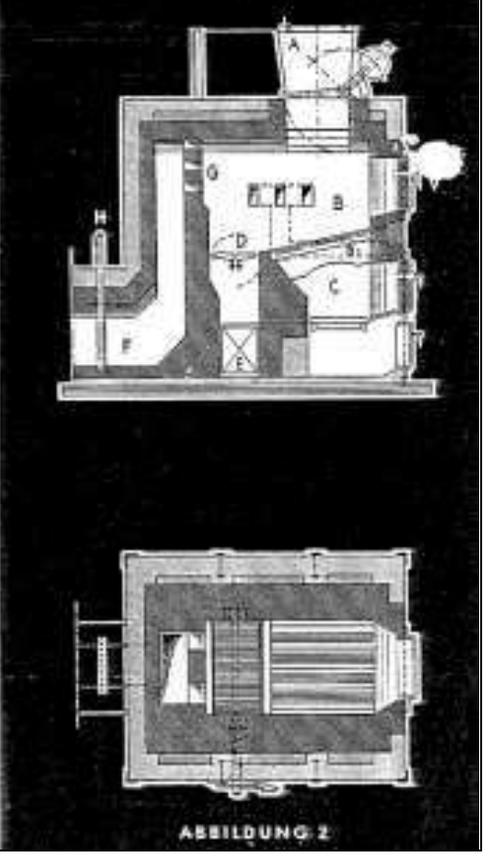

ABBILDUNG 2

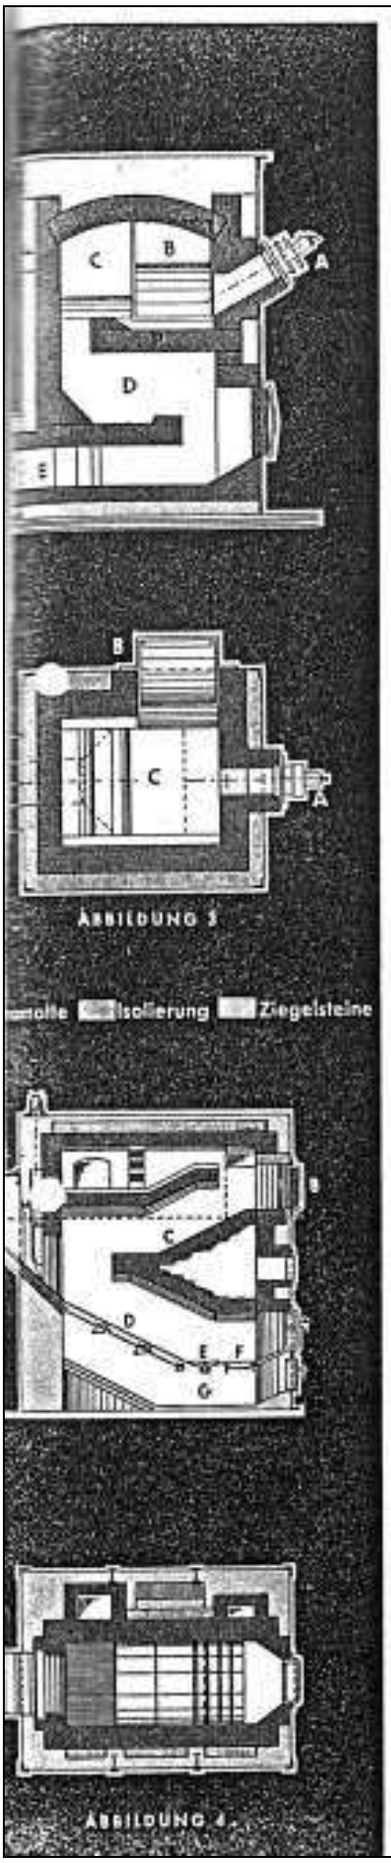
Document 161: continued.



VIER TOPF-OFENTYPEN

ARCHIWUM

Der Sputum-Vernichtungsofen SV

Abb. 3

ist mit Schmiedeeisen umkleidet. Dieser Mantel schützt das Ofeninnere vor Beschädigung. Gleichzeitig sind an ihm der Gasbrenner A und der Aufgabekasten B angebracht. Die Schamotteplatte P trennt den Verbrennungsraum C vom Nachverbrennungsraum D und dem zum Schornstein führenden Rauchgaskanal E. Die zu vernichtenden Papp-Sputum-Gefäße werden durch den Aufgabekasten auf die Schamotteplatte gebracht, auf der sie verbrennen. Der Nachverbrennungsraum gewährleistet einen guten Ausbrand der Abgase und damit einen rauch- und geruchschwachen Betrieb • Der Rauchkanalschieber F, der außerhalb der Ofen-Ummantelung angebracht ist, dient dem Regeln der Zugstärke. Zwischen Blechmantel und Schamottemauerung wird eine Isolierung aus Kieselgur angebracht. Diese unterbindet die Wärmeausstrahlung.

Der Müll-Verbrennungsofen MV

Abb. 4

vernichtet bei geringem Brennstoffverbrauch schnell, sicher, rauch- und geruchschwach den täglich anfallenden Müll in Kaufhäusern, Industriewerken, Hotels, Markthallen usw. Der Ofen hat einen Backsteinmantel mit einer starken schmiedeeisernen Verankerung. Eine kleine Hilfsfeuerung F heizt den Ofen vor der Verbrennung hoch • Das nasse Müllgut wird durch die Tür B auf den Schamotterost C und der trockene Müll durch den Kasten A auf den Rost D geschüttet. Der Drehrost E befördert nach dem Brand die Aschenrückstände leicht nach dem Aschefall G.

Wert und Leistungsfähigkeit der TOPF-Öfen werden in einem Bericht gekennzeichnet:

„In den letzten 4 Wochen sind von der Städtischen Straßenreinigung ungeheure Berge von alten Sofas und Matratzen angeliefert worden, die schnellstens und zwar in 24stündiger Schicht verbrannt werden mußten. In der Zeit hat unser Ofen dauernd binnen 24 Stunden 120 – 130 Matratzen eingeäschert und dabei riesige Mengen Drahtsprungfedern ans Licht gebracht."

Fahrbarer Verbrennungsofen
System „Topf“

Abbildung 3. Längsschnitt.

Abbildung 4. Querschnitt.

Der nachstehend beschriebene Ofen ist fahrbar eingerichtet, wodurch er den Vorzug hat, daß er unmittelbar an das Verbrennungsobjekt herangefahren werden kann. Der Ofen ist besonders für Großgrundbesitzer und Viehzüchter in weiten Steppen unentbehrlich, da in der Hauptsache an Tränkstellen gefallenes Vieh sofort vernichtet werden kann, ohne dasselbe erst weit zu transportieren.

Die Vorzüge dieses Ofens sind leichte und bequeme Beförderungsweise, leichte Bedienung, große Haltbarkeit und stabiles Fahrgestell. Der Kessel wird innen mit Ia Schamottematerialien ausgekleidet, daher geringe Ausstrahlung. Dieser Ofen kann auch mit Öl- und Gasfeuerung eingerichtet werden.

Bericht.

des H-Oscha. P o l l o k in der Eigenschaft als Sachbearbeiter für baupolizeiliche Angelegenheiten.

Am Schornstein des Krematoriums im K.L. Auschwitz hat sich der Kamineinband gelöst. Dieses ist auf eine unsachgemässe Ausführung, sowie teilweise Überhitzung des Schornsteines zurückzuführen. Die Einbände sind nicht dem Zweck entsprechend als Rahmen ausgebildet und sind deshalb unwirksam. Da der Schornstein bereits starke Risse aufweist, die zwar äusserlich wieder verfugt, im Mauerwerk meines Erachtens nach noch vorhanden sind, besteht die Gefahr, dass der Schornstein bei stärkerem Wind einstürzen kann. Um unabsehbare Folgen zu vermeiden, bitte ich den Leiter der Zentralbauleitung veranlassen zu wollen, dass sofort Massnahmen getroffen werden, um die Mängel zu beseitigen. Dabei wäre zu beachten, dass alle Einbände entfernt und durch Rahmeneinbände sach- und handwerksgemäss ersetzt werden.

Auschwitz, den 30-Mai. 1942

Pollok

H-Oberscharführer.

Standfestigkeitsberechnung eines gemauerten Schornsteins

94 A

von h = 15 m Höhe über Gelände und 2 r_o = 1,20 m oberer lichter Weite.

Es sind bestimmt: S für die Gewichte von Schaft, Sockel und Futter, C für die Lagerfugen, D für die Grundbausohle, E für gefährliche Querschnitte bei Einführung von Fuchs- oder Räumöffnungen.

Bauherr: Zentralbauleitung der Waffen SS und Polizei in Auschwitz O/S.

Bauunternehmer:

Bauort: Lager Auschwitz Dampfkesselnummer:

Der Schornstein dient zum Betriebe einer Anlage.

Berechnungsgrundlagen:

Grundlagen für die Ausführung freistehender Schornsteine DIN 1056, Blatt 1-2 u. DIN 1057 (Ausg. 1940). Erläuterung des Vordrucks in: H. Jahr, Die Fabrikschornsteine, 8. Auflage, Verlag Otto Hammerschmidt, Hagen i. W., 1940.

Abmessungen und Baustoffe: (vgl. anliegende Zeichnung Nr. vom 19)

Schaft

Schafthalbmesser an der Mündung | innen r_o = 0,60 m | Unterer innerer Schafthalbmesser r = 0,85 m

außen R_o = 0,84 m | Unterer äußerer Schafthalbmesser R = 1,09 m

Die Schafthöhe h_s = 12 m | Die Halbmesserzunahme für 1 m Höhe beträgt 0,04 cm

Mauerwerk: h'_s 12 m -Ziegel; Ziegel-Druckfestigk.: σ_z 150 kg/cm²; Mauerwerks-Druckfestigk.: σ_s 7 kg/cm²

Mauerwerk: h''_s -Ziegel; Ziegel-Druckfestigk.: σ_z kg/cm²; Mauerwerks-Druckfestigk.: σ_s kg/cm²

laut beil. Prüfungszeugnis Mörtelmischungsverhältnis: - Raumteile Zement zu - Rtl. Kalk zu 1:3 Rtl. Sand.

Mauerwerks-Raumgewicht: γ_1 = 1800 kg/m³; größte zulässige Druckspannung: $\sigma_{d\,zul}$ 7 kg/cm²,

Mauerwerks-Raumgewicht: γ_2 = kg/m³; größte zulässige Druckspannung: $\sigma_{d\,zul}$ kg/cm².

Sockel

Höhe: h_1 = 3 m Querschnittsform: außen: Quadrat

Mauerwerk: -Ziegel innen:

Ziegeldruckfestigkeit: σ_z = 150 kg/cm²; Mauerwerks-Druckfestigkeit: σ_s = 7 kg/cm²; Mörtelmischungsverhältnis: 1:3 Rtl. Zement zu - Rtl. Kalk zu - Rtl. Sand; Mauerwerks-Raumgewicht: γ = 1800 kg/m³; größte zulässige Druckspannung: $\sigma_{d\,zul}$ = 7 kg/cm².

Grundbau

Form der Sohlenfläche: qm ; Tiefe: h_2 2,6 m; Baustoff: -Beton, Mischungsverhältnis = 1:6 ;

Mauerwerk: normal- -Ziegel, Mörtelmischung = 1:4:13 ; Raumgewicht: γ = 1800 kg/cm³;

größte zulässige Druckspannung für Mauerwerk: $\sigma_{d\,zul}$ = 10 kg/cm²; desgl. für Beton: $\sigma_{d\,zul}$ = 25 kg/cm².

Isoliermantel

Höhen:	4,60 m,	12 m,	m,	m,	m,	m,
Wandstärken:	12 cm,	12 cm,	cm,	cm,	cm,	cm,

Baustoff: Schamott - Normalzieg -Ziegel; Raumgewicht: γ = 1900 / 1800 kg/cm².

Erläuterung zur Berechnung des Schornsteins:

1. **Gewichtsberechnung.** Das Gewicht einer Trommel (Schaft- oder Sockelteil von gleicher Wanddicke) ist

$$G = x \cdot d \cdot z\,(R_o + r) \cdot \gamma \quad \text{kg},$$

wobei d die Wanddicke, z die Trommelhöhe und R_o und r den äußeren oberen bzw. inneren unteren Trommelhalbmesser bedeuten. Außerdem ist bei Kreisquerschnitt x = π = 3,1416, bei Achtecken x = 3,314, bei Quadraten x = 4,00.

2. **Windlastberechnung.** Ist h (in m) die Schornsteinhöhe über Gelände, dann ist die Windlast, bezogen auf 1 m² Achsschnittfläche

$$w = 120 + 0{,}6 \cdot h \text{ (in kg/m²)}.$$

Ist ferner bei runden Schornsteinen n = 0,67, bei achteckigen n = 0,71, bei viereckigen n = 1,0, dann ist der gesamte Winddruck auf die Säule $W = n \cdot w \cdot F$ und das Winddruckmoment $M = W \cdot s$, wenn F die senkrechte Querschnittfläche und s den Abstand des Schwerpunktes derselben über der betrachteten Lagerfuge bezeichnen.

Nachdruck, auch auszugsweise, verboten. Erläuterungen dazu sind enthalten in Jahr: Die Fabrikschornsteine 8. Auflage 1940. Verlag Otto Hammerschmidt, Hagen i. Westf.

			G 3 =	41.472
	Insgesamt:	G o =		111.547

Document 177: continued.

C

Berechnung der Fugenspannungen

Für jeden Schornsteinquerschnitt ist h die Höhe des darüberliegenden Schornsteinteiles in m.
Für die Mündung des Schornsteines ist R_o = 0,84 m, r_o = 0,60 m.

Für nebenbezeichn. Schornsteinteile ist	Säule über Fuge I, h = 12 m	Säule über Fuge , h = m
Unterer äußerer Halbmesser R in m	(0,04x12+1,70):2 = 1,09	
Unterer innerer Halbmesser r in m	1,09−0,25 = 0,84	
1. Gewicht G über der Fuge in kg	4x12x0,25(0,84+0,85)x1800=36.504	
2. Windlast W in kg	125(0,84+1,09)x12=2.895	
Windlastmoment M in kgm	$42(1,09+1,68)x12^2$=16.753	
3. Ausschl. des Druckmittelpunktes: $a = \frac{M}{G}$ in m	$\frac{16753}{36504}$ = 0,45	
4. Der betracht. Querschn. F in m²	$4(1,09^2-0,85^2)$ = 1,88	
5. Kleinste Kernweite k in m	$0,236x1,09(1+\frac{0,85^2}{1,09^2})$=0,42	
6. Zulässige Größe des Ausschlages = zweite Kernweite e	0,55x1,09+0,34x0,85=0,89	
Da a kleiner ist als e, so ist die Bedingung erfüllt, daß sich die Fugen nicht weiter als bis zur Schwerpunktachse öffnen.		
7. Pressung durch Eigengewicht σ_o $\sigma_o = G : (F \cdot 10000)$ in kg/cm²	$\frac{36504}{18800}$ = 1,94	
8. Hilfsspannungen in kg/cm² $\sigma' = \sigma_o\left(1+\frac{a}{k}\right)$	$1,94(1+\frac{0,45}{0,42})$ = 4,01	
8. Hilfsspannungen in kg/cm² $\sigma'' = \sigma_o\left(1-\frac{a}{k}\right)$	$1,94(1-\frac{0,45}{0,42})$ = 0,14	
9. Größte Kantenpress. in kg/cm² $\sigma_m = \sigma'' + \sigma'\left(\frac{a-k}{e-k}\right)^2$	$4,01+0,14(\frac{0,45-0,42}{0,89-0,42})^2$=4,01	
10. Zulässige Kantenpress. in kg/cm² $\sigma_d = 0,40 \cdot \sigma_{dzul} + 0,15\ h'$	0,4x7+0,15x12 = 4,60	
Für nebenbezeichn. Schornsteinteile ist	**Säule über Fuge II, h = 3 m**	**Säule über Fuge , h = m**
Unterer äußerer Halbmesser R in m	(0,04x3+2,18+26) = 1,28	
Unterer innerer Halbmesser r in m	1,28−0,38 = 0,90	
1. Gewicht G über der Fuge in kg	4x3x0,38(1,22+0,9)x1800=	17406
2. Windlast W in kg	95x2,44x3 = 695	
Windlastmoment M in kgm	16753+3x(2895+695)=26479	
3. Ausschl. des Druckmittelpunktes: $a = \frac{M}{G}$ in m	$\frac{26479}{53910}$ = 0,49	
4. Der betracht. Querschn. F in m²	$4x(1,28^2-0,90^2)$ = 3,32	
5. Kleinste Kernweite k in m	$0,236x1,28(1+\frac{0,90^2}{1,28^2}$= 0,45	
6. Zulässige Größe des Ausschlages = zweite Kernweite e	0,55x1,28+0,34x0,90= 1,01	
Da a kleiner ist als e, so ist die Bedingung erfüllt, daß sich die Fugen nicht weiter als bis zur Schwerpunktachse öffnen.		
7. Pressung durch Eigengewicht σ_o $\sigma_o = G : (F \cdot 10000)$ in kg/cm²	$\frac{53910}{33200}$ = 1,62	
8. Hilfsspannungen in kg/cm² $\sigma' = \sigma_o\left(1+\frac{a}{k}\right)$	$1,62(1+\frac{0,49}{0,45})^2$ = 3,38 = 3,53	
8. Hilfsspannungen in kg/cm² $\sigma'' = \sigma_o\left(1-\frac{a}{k}\right)$	$1,62(1-\frac{0,49}{0,45})$ = 0,15	
9. Größte Kantenpress. in kg/cm² $\sigma_m = \sigma'' + \sigma'\left(\frac{a-k}{e-k}\right)^2$	$3,38+0,15(\frac{0,49-0,45}{1,01-0,45})^2$= 3,53	
10. Zulässige Kantenpress. in kg/cm² $\sigma_d = 0,40 \cdot \sigma_{dzul} + 0,15\ h'$	0,4x10+0,15x3 = 4,45	

Document 177: continued.

Beanspruchung der Grundbausohle

D

Tiefe des Grundbaues h_2 = 2,6o m

Durchmesser der runden oder Abstand zweier gegenüberliegender Seiten der eckigen Grundplatte D = 3,6o m

1. **Fläche der Grundbausohle** F_2 = 12,96 m

Inhalt des Grundbaues V_2 = 2o,16 cbm

m³

G_1 = Schaftgewicht = 36.5o4,- kg

G_2 = Inhe-Behälter { Leergewicht = ... kg; gefüllt J = m³ = ... kg

G_3 = Sockelgewicht = 17.4o6,- kg

G_4 = Isoliermantel = 16.265,- kg

G_5 = Grundbaugewicht = 41.472,oo kg

G_6 = ... kg

2. **Gesamt-Schornsteingewicht** Σ G = 111.647,oo kg

3. **Windmoment**, bezogen auf die Grundbausohle

$M_2 = 26.479+2,6(2.895+695)$

35.813 kgm

4. Der **Ausschlag des Druckmittelpunktes** von der Mitte ist:

$a_2 = \frac{M_2}{\Sigma G} = \frac{35,813}{111,647}$ = o,32 m

5. Die **kleinste Kernweite** der Grundplatte ist:

$k_2 =$ o,118x3,6 = o,42 m

Da $a_2 < k_2$, hebt sich die Grundplatte nicht vom Boden ab!

6. **Beanspruchung durch Eigenlast:**

$\sigma_0 = \frac{G \text{ (in kg)}}{F \text{ (in m}^2) \cdot 10000} = \frac{111.647}{129.6oo}$ = o,86 kg/cm²

7. **Randspannung an der Windschattenseite:**

$\sigma_2 = \sigma_0 \left(1 + \frac{a_2}{k_2}\right) =$ o,86$\left(1+\frac{o,32}{o,42}\right)$ = 1,5o

Art des Baugrundes: ...

Zulässige Bodenbeanspruchung: σ_{zul} 2 kg/cm²

Bemerkungen:

Der Grundbau besteht aus dem Inhalte der Bodenplatte und dem Inhalte der Pyramide oder Stufen abzüglich der Aussparungen. Der Inhalt der Pyramide ist $= \frac{4}{3} h'' (R_2^2 + R\, r_1 + r_1^2)$, wenn h'' die Höhe der Pyramide, R_2 und r_1 die Halbmesser der einbeschriebenen Kreise des unteren und oberen Querschnittes der Pyramide sind.

Ist W = Windlast und M = Windlastmoment auf den Säulenschaft, W_1 = Windlast und M_0 = Windlastmoment auf die Sockelsohle, so ist das auf die Grundbausohle wirkende Windlastmoment

$M_2 = M_1 + h_2 (W + W_1)$

Hat der Schornstein keinen Sockel, so ist

$M_2 = M + h_2 W$

Die kleinste Kernweite der Grundplatte beträgt bei:
quadr. Form $k_2 = 0,118 \cdot D$
achteck. „ $k_2 = 0,122 \cdot D$
runder „ $k_2 = 0,125 \cdot D$

Erklärung

Bauherr und Bauausführender übernehmen die Gewähr dafür, daß die in der Standfestigkeitsberechnung eingesetzten Gewichte mit der Wirklichkeit übereinstimmen und die zu verwendenden Baustoffe hinsichtlich ihrer Güte und Fähigkeit unseren Angaben entsprechen und technisch richtig angewandt werden.

B e r i c h t

des ᛋᛋ-Obersturmführer Pollok in der Eigenschaft
als Sachbearbeiter für baupolizeiliche Angelegenheiten.

Bei der baupolizeilichen Überwachung der Bauarbeiten am Krematorium wurde festgestellt, daß der alte Schornstein in der Horizontal- sowie Vertikalrichtung neue Risse erhalten hat, die zum Einsturz des Schornsteines führen müssen. Dieses ist darauf zurückzuführen daß der Schornstein weiterhin übermässig beansprucht wurde, trotzdem die Zentralbauleitung der Waffen-ᛋᛋ und Polizei mit Schreiben vom 4.Juni 1942 Bftgb.Nr. 8195/42/Po/Qu. an die Kommandantur des K.L. die Benützung desselben verboten hat.

Ich bitte den Dienststellenleiter der Zentralbauleitung die weitere Benützung des Schornsteines erneut zu verbieten und veranlassen zu wollen, daß der Schornstein sofort abgetragen wird, da sonst unabsehbare Folgen entstehen können.

Auschwitz, den 6.Juli 1942

13. August 1942

Bftgb. - Nr. 11775 /42/Ki/Mü 54/11

Betr.: K.L. Auschwitz, neue Schornsteinanlage Krematorium
Bezug: Telefongespräch zwischen ᛋᛋ-Hstuf. (S) Bischoff und ᛋᛋ-Hstuf. Mulka am 12.8.1942, 12[00] Uhr
Anlg.: - . -

An die
Kommandantur des K.L.

Auschwitz O/S.

Auf Grund o.a. Telefongespräches wurde der Kommandantur mitgeteilt, dass durch das zu rasche Ausheizen der neuen Schornsteinanlage des Krematoriums (essind alle 3 Öfen in Betrieb) bereits Schäden am Mauerwerk aufgetreten sind.

Da die Inbetriebsetzung der 3 Verbrennungsöfen noch vor Erhärtung des Kaminmauerwerksmörtels in vollem Umfange erfolgte, muss jede weitere Verantwortung für das Bauwerk abgelehnt werden.

Der Leiter der Zentralbauleitung
der Waffen-ᛋᛋ und Polizei Auschwitz

ᛋᛋ-Hauptsturmführer (S)

Betr.: Baracken für die politische Abteilung - BW 92 -
Bezug: persönliche Rücksprache zwischen Ustuf.Grabner und Ustuf.(F) Kirschnack
Anlg.: keine

An den Leiter der
SS-Standortverwaltung
SS-Obersturmbf. S o k o l

K.L. Auschwitz

Die hiesige Dienststelle teilt mit, dass der Standplatz der beiden Baracken für die politische Abteilung, insbesondere der Schweizer Baracke, von der Voraussetzung ausgehend festgesetzt wurde, dass das Krematorium I seinen Betrieb vollständig einstellen wird, wie dies auch bei der o.a. Rücksprache von SS-Ustuf.Grabner versichert wurde.

Nachdem die Arbeiten an den Baracken fast beendet sind, wurde festgestellt, dass das Krematorium trotzdem neuerdings in Betrieb genommen wurde.

Die leichte Entzündbarkeit dieser Bauwerke verlangen die Ausserbetriebsetzung des Krematoriums I, widrigenfalls für sich daraus ergebende Feuerschäden jede Verantwortung abgelehnt werden muss.

BETRIFFT: Ihr Schreiben v. 22.10.41, Bestellung von Topf-Dreimuffel-Öfen, Saugzug-Anlagen und Topf-Müllverbrennungs-Ofen.

IHR ZEICHEN: Bftg.-Nr.215/41 Ho.

UNSERE ABTEILUNG: D IV/Prf.

Auftrag Nr. 41/2249/1.

Wir danken Ihnen bestens für den uns erteilten Auftrag auf Lieferung von

5 Topf-Dreimuffel-Einäscherungs-Öfen mit Druckluft-Anlage
2 Sarg-Einführungs-Vorrichtungen mit Schienen-Anlage für 5 Öfen
3 Topf-Saugzug-Anlagen
1 Topf-Müll-Verbrennungs-Ofen
Rauchkanal-Anlage.

Den Auftrag nehmen wir an aufgrund unseres beiliegenden Kostenanschlages und dessen Bedingungen zum Gesamtpreise von RM 51 237.--.

Unsere Lieferung:
a) Für die 5 Topf-Dreimuffel-Einäscherungs-Öfen die gesamten Schamotte- und Isoliermaterialien, die guß- und schmiedeeisernen Armaturen, die Druckluft-Anlagen mit Motoren und die Kosten zweier Monteure für die Beaufsichtigung der Bauarbeiten.

Document 186: Order confirmation by J.A. Topf & Söhne to the SS Construction Office at Auschwitz of 4 November 1941 regarding 5 coke-fired triple-muffle cremation furnaces for Crematorium II at Birkenau with auxiliary equipment and a waste incinerator. Source: RGVA, 502-1-313, pp. 81-83.

J.A.TOPF & SÖHNE ERFURT

TAG	BLATT

EMPFÄNGER Bauleitung der Waffen-SS und Polizei, Auschwitz /O.-S.

82

b) Die 2 Sarg-Einführungs-Vorrichtungen mit Verschiebewagen, einschließlich der Schienen-Anlage für die 5 Stück Einäscherungs-Öfen.

c) Die 3 Topf-Saugzug-Anlagen mit Motoren und die Monteurgestellung zum Einbau der Anlagen.

d) Für die Topf-Müll-Verbrennungs-Anlage die gesamten Schamotte- und Isoliermaterialien, einschließlich der guß- und schmiedeeisernen Armaturen, einschließlich Stellung eines Monteurs zur Beaufsichtigung der Bauarbeiten.

e) Zur Rauchkanal-Anlage die gesamten Schamottematerialien und Stellung eines Monteurs.

Bauseitige Lieferung:

Zu den Öfen und der Rauchkanal-Anlage die gesamten Mauermaterialien, wie Ziegelsteine, Sand, Kalk und Zement, deren Mengen aus dem Kostenanschlag zu ersehen sind, sowie auch die gesamten, schmiedeeisernen Verankerungs-Eisen kostenlos für uns.

Ferner stellen Sie unseren Monteuren ohne Kosten für uns genügend Helfer zur Verfügung.

Die von uns vorgesehene Bauzeit für die Anlagen darf 8 Wochen nicht überschreiten, da wir die Stellung unserer Leute nur für diese Zeit berechnet haben. Sollte die vorgesehene Bauzeit überschritten werden, sind die abgeleisteten Stunden im Tagelohn zu verrechnen.

Da die fortgeschrittene Jahreszeit den Bau der Öfen in ungeheizten Räumen nicht zuläßt, so wollen Sie für baldige Erstellung des Ofenraumes und für Heizung desselben Sorge tragen.

Lieferzeit:
Die von Ihnen gewünschte Lieferzeit von 3 Monaten für die Öfen werden wir versuchen einzuhalten. Dabei ist Voraussetzung, daß in der Materialbeschaffung keine Stockung eintritt und uns keine weiteren Arbeitskräfte entzogen werden.

Wir benötigen 6 Frachtbriefe mit den erforderlichen Vermerken Ihrerseits, um deren baldige Zustellung wir Sie bitten.

Kennziffer:
Wir bitten, dafür zu sorgen, daß die Bekanntgabe einer solchen über 17 600 kg schnellstens erfolgt.

Zeichnungen:
Für die Erstellung der Ofenfundamente sowie zur Anfertigung der Verankerungs-Eisen erhalten Sie von uns in Kürze die erforderlichen Zeichnungen.

Der Gesamtplan mit eingezeichneten Öfen, Rauchkanal- und Entlüftungs-Anlage, desgleichen eine Ofenzeichnung des Dreimuffel-Ofens liegt bei.

Ausführung:
Erwähnen möchten wir, daß die Einäscherungskammern in den Öfen jetzt größer gebaut werden als bei den bisherigen Öfen. Hierdurch wollen wir eine größere Leistung erreichen. Aus dem gleichen Grunde haben wir auch statt 2 Saugzug-Anlagen deren 3 vorgesehen, dabei aber auch berücksichtigt, daß gefrorene Leichen zur Einäscherung gelangen, die mehr Heizmaterialaufwand bedingen, wodurch die Abgasmenge sich erhöht.- Wir sichern Ihnen die Erstellung einer sachgemäßen und gut arbeitenden Anlage zu und empfehlen uns mit

Aktenvermerk

Betr.: Anwesenheit von Obering. Prüfer der Fa. Topf u. Söhne Erfurt, bezüglich Ausbau der Einäscherungsanlagen im K.G.L. Auschwitz

Vorgang: Herr Ing. Prüfer sprach am 19.8.1942 um 14,oo Uhr bei hiesiger Dienststelle vor, um über den Einbau von 5 Stück 3 Muffel-Einäscherungsöfen im Krematorium des K.G.L. und Neuanlage von 2 Stück 3 Muffelöfen in einfacher Bauweise lt. Plan Nr. D 59 - 570 und Nr. D 59 599 die erforderlichen Einzelheiten zu besprechen.

Hierbei wurde folgendes festgelegt:

1.) Spätestens 26. - 27. August trifft der Monteur Holik aus Buchenwald hier ein, der Monteur Koch in ca. 14 Tagen. Mit dem Aufbau der 5 Stück 3 Muffelöfen im K.G.L. wird sofort begonnen. Die Fa. Köhler Kyslowitz führt die Ausmauerung der Öfen und Fuchse, sowie die Errichtung des Schornsteines lt. Plänen und Angaben der Fa. Topf u. Söhne durch.

2.) Bezüglich Aufstellung von je 2 Dreimuffelöfen bei den "Badeanstalten für Sonderaktionen" wurde von Ing. Prüfer vorgeschlagen, die Öfen aus einer bereits fertiggestellten Lieferung nach Mogilew abzuzweigen und wurde sogleich der Dienststellenleiter welcher beim SS-Wirtschafts-Verwaltungshauptamt in Berlin anwesend war, hiervon tel. in Kenntnis gesetzt und gebeten, das weitere veranlassen zu wollen.

3.) Bezüglich Errichtung eines 2. Krematoriums mit 5 Dreimuffelöfen, sowie Be- und Entlüftungsanlagen muß erst das Ergebnis der bereits laufenden Verhandlungen mit dem Reichssicherheitshauptamt bezügl. Zuteilung von Kontingenten abgewartet werden.

- 2 -

Document 187: "File memo" by SS-Untersturmführer *Ertl of 21 August 1942. Source: RGVA, 502-1-313, pp. 159f.*

- 2 -

4.) Nach Auschwitz wurden von der Fa. Topf u. Söhne irrtümlich die Teile eines Doppelmuffel-Einäscherungsofens gesandt, welche jedoch für Mauthausen bestimmt waren.
Ing. Prüfer schlägt vor, den Ofen hier zur Aufstellung zu bringen. Die fehlenden 2 Einführtüren und 2 Aschenentnahmetüren können inzwischen der Lieferung der 5 Dreimuffel-Einäscherungsöfen entnommen werden.

5.) Die Schäden in dem neu gemauerten Schornstein für das bestehende Krematorium wurden gemeinsam mit Herrn Köhler und H-Unterscharführer Kirschnek besichtigt und die zu ergreifenden Maßnahmen besprochen. - Da das Schornsteinfutter infolge der großen Hitze arbeitet, muß es oben frei durchgehen und darf nicht mit dem Außenmantel fest verbunden sein.

6.) Am Donnerstag den 20.August 1942 wurde gemeinsam mit H-Strm. Janisch u. Herrn Köhler die Baustelle des 5 Dreimuffelofens im K.G.L. besichtigt, und die erforderlichen Einzelheiten durchbesprochen.

7.) Ing. Prüfer bat um schriftlichen Auftrag über die Lieferung der 2 Stück 3 Muffel- und den Doppelmuffel-Einäscherungsofen, sowie um baldige Mitteilung, ob die Öfen der Lieferung Mogilew abgezweigt werden können.

8.) Zum Antransport des fehlenden Schamotte- und sonstigen Materiales sind der Fa. Topf u. Söhne sogleich 10 Frachtbriefe einzusenden.

Trawniki, den 2. Sept. 1943. 147

Betr. Einäscherungsofen für Krematorium
Bez. Verteiler des SS Wirtschafters in Krakau v.18.8.43.
Az. 6/2 C 2 / 2a / Ma / La.
Anlage: 1

An die Zentralbauleitung
der Waffen SS u. Polizei

L u b l i n

Anliegend wird der Verteiler des SS Wirtschafters zurückgesandt. Ein Krematorium ist im hiesigen Lager nicht vorhanden. Dieser Zustand wurde bereits öfters beanstandet. Die Errichtung eines Krematoriums wäre jedoch dringend erforderlich. Ob allerdings die dem Amt C 3 zur Verfügung stehenden Topf-Einäscherungs Öfen für Trawniki in Frage kommen könnten, müsste von dort entschieden werden.

AZ/WOM

Betriebsvorschrift über die

„TOPF"- Saugzuganlage

Falls der Zug im Ofen nicht ausreicht, muss die am Schornstein eingebaute Saugzuganlage in Betrieb genommen werden.

Hierbei beachten, dass zuerst der Motor angestellt wird und dann erst darf die Drehklappe im Schornstein geschlossen werden. Die Wasserzufuhr zum wassergekühlten Lager muss auch sofort laufen.

Nach Schluss des Einäscherungsbetriebes muss zuerst die Drehklappe im Schornstein geöffnet werden und dann den Motor und die Wasserzufuhr abstellen.

Zu beachten ist fernerhin, dass immer genügend Wasser im Behälter vorhanden ist.

---

ARCHIWUM

Betriebsvorschrift des koksbeheizten Topf-Doppelmuffel-Einäscherungsofen.

Vor Beschickung der beiden Koksgeneratoren mit Koks müssen die beiden Rauchkanalschieber am Ofen geöffnet werden, desgl. auch der Hauptrauchkanalschieber bzw. die Drehklappe am Schornstein.

Nunmehr kann in den beiden Generatoren Feuer angefacht und unterhalten werden, hierbei beachten, dass die Sekundärverschlüsse rechts und links der Ascheentnahmetüren (Koksgenerator) geöffnet sind.

Nachdem die Einäscherungskammer gut rotwarm (ca 800°C.) ist können die Leichen hintereinander in die beiden Kammern eingefahren werden.

Jetzt ist es zweckmässig das seitwärts am Ofen stehende Druckluftgebläse anzustellen und ca 20 Minuten laufen zu lassen. Hierbei ist zu beobachten, ob zuviel oder zu wenig Frischluft in die beiden Kammern eintritt.

Die Regulierung der Frischluft erfolgt durch die Drehklappe die sich in der Luftrohrleitung befindet. Weiterhin müssen die rechts und links der Einführtüren angeordneten Lufteintritte, halb geöffnet werden.

Sobald die Leichenteile vom Schamotterost nach der darunter liegende Ascheschräge gefallen sind, müssen diese mittels der Kratze nach vorn zur Ascheentnahmetür gezogen werden. Hier können diese Teile noch 20 Minuten zum Nachverbrennen lagern. Dann wird die Asche in den Aschebehälter gezogen und zur Abkühlung beiseite gestellt.

Zwischendurch werden neue Leichen in die Kammern nach einander eingeführt.

Die beiden Koksgeneratoren müssen von Zeit zu Zeit mit Brennstoff beschickt werden.

Jeden Abend muss der Generatorrost von den Koksschlacken befreit und die Asche herausgenommen werden.

Zu beachten ist ferner, das nach Betriebsschluss, sobald der Generator leer gebrannt ist und Glutteile nicht mehr vorhanden sind, alle Luftschieber und Türen desgl. auch die Rauchkanalschieber am Ofen geschlossen sein müssen um den Ofen nicht auszukühlen.

Nach jeder Einäscherung steigt die Temperatur im Ofen. Daher bitte beachten, dass die Innentemperatur nicht über 1100°C kommt (Weissglut).

Diese Temperatursteigerung kann durch Lufteinblasen verhindert werden.

---

26. SEP. 1941

Document 210: J.A. Topf & Söhne, "Operating instructions for the Topf coke-fired double-muffle cremation furnace." 26 September 1941. Source: APMO, BW 11/1, p. 3.

- 5 -

Barackenlager: Für Wachtruppe (1 Bataillon) werden 6 Luftwaffenbaracken, 1 Wirtschaftsbaracke, 1 Waschbaracke und 1 Abortbaracke aufgestellt. Die Baracken erhalten elektr. Licht, Wasseranschluss und Ofenheizung.
(Die Lieferung der Baracken wurde vom Hauptamt Haushalt und Bauten Amt II zugesagt, jedoch sind diese bis heute noch nicht eingetroffen).-

Lagerhaus: Ausserhalb des Lagers am Anschlussgleis für Lebensmittellagerung mit Rampe. Planung noch nicht durchgeführt.

Nebenanlagen: Die Wasserversorgung erfolgt durch 3 eigene Brunnenanlagen mit Pumpanlage für Nutzwasser und 3 Brunnen für Trinkwasser. Die Beseitigung der Abwässer erfolgt durch je 3 Leitungen an der Breitseite des Lagers. Über den Abflußleitungen sind die Wasch- und Abortbaracken angeordnet. Die 3 Leitungen werden zusammengefasst, die Abwässer in 3 Frischwasserklärgruben geklärt und durch einen Vorflutgraben zur Weichsel geführt.-Die Stromzufuhr erfolgt von der Dachpappenfabrik in Birkenau bis zum Transformator im Quarantänelager - Eingangsgebäude als Freileitung, von dort wird der Strom in Kabel weitergeführt.
Die Lagereinfriedung besteht aus ca 3,2o m hohen Betonpfosten in 3,5o m Abstand, an welcher der mit 2000 Volt Hochspannung geladene Stacheldraht angebracht wird. Um ein Untergraben des Drahtzaunes zu verhindern, wird eine Erdsicherung eingebaut.
Anschliessend wäre zu bemerken, dass die neue Zufahrtsstrasse vom K.L. die Reichsbahn schienengleich durchkreuzt. Diesbezügliche Verhandlungen mit der Reichsbahn sind im Gange, ebenso bezüglich des Gleisanschlusses.-

Hilfsbetriebe: Infolge des grossen Belages (125000 Gefangene) wird ein Krematorium errichtet. Es enthält 5 Stück Muffelöfen mit je 3 Muffeln für 2 Mann, sodass in einer Stunde 60 Mann eingeäschert werden können. Ausserdem wird ein Leichenkeller und 1 Müllverbrennungsofen erstellt. Das Krematorium gelangt auf dem Gelände des K.-L. zur Aufstellung.

BETRIEBSVORSCHRIFT

des koksbeheizten Topf-Dreimuffel-

Einäscherungsofen

Vor Beschickung der beiden Koksgeneratoren mit Koks muss der Rauchkanalschieber am Ofen geöffnet werden.

Nunmehr kann in den beiden Generatoren Feuer angefacht und unterhalten werden, hierbei ist zu beachten, dass die Sekundärverschlüsse rechts und links der Ascheentnahmetüren (Koksgeneratoren) geöffnet sind.

Nachdem die Einäscherungskammern gut rotwarm (ca. 800°C) sind können die Leichen hintereinander in die drei Kammern eingefahren werden.

Jetzt ist es zweckmässig das seitwärts am Ofen stehende Druckluftgebläse anzustellen und ca. 20 Minuten laufen zu lassen. Hierbei ist zu beobachten, ob zuviel oder zu wenig Frischluft in die drei Kammern eintritt.

Die Regulierung der Frischluft erfolgt durch die Drehklappe die sich in der Luftrohrleitung befindet. Weiterhin müssen die rechts und links der Einführtüren angeordneten Lufteintritte halb geöffnet werden.

Sobald die Leichenteile vom Schamotterost nach der darunter liegende Ascheschräge gefallen sind, müssen diese mittels der Kratze nach vorn zur Ascheentnahmetür gezogen werden. Hier können diese Teile noch 20 Minuten zum Nachverbrennen lagern. Dann wird die Asche in den Aschebehälter gezogen und zur Abkühlung beiseite gestellt.

Zwischendurch werden neue Leichen in die Kammern nach einander eingeführt.

Die beiden Koksgeneratoren müssen von Zeit zu Zeit mit Brennstoff beschickt werden.

Jeden Abend müssen die Generatorroste von den Koksschlacken befreit und die Asche herausgenommen werden.

Zu beachten ist ferner, das nach Betriebsschluss, sobald die Generatoren leer gebrannt und Glutteile nicht mehr vorhanden sind, alle Luftschieber und Türen, desgl. auch der Rauchkanalschieber am Ofen geschlossen sein müssen um den Ofen nicht auszukühlen.

Nach jeder Einäscherung steigt die Temperatur im Ofen. Daher bitte beachten, dass die Innentemperatur nicht über 1000°C. kommt (Weissglut).

Diese Temperatursteigerung kann durch Lufteinblasen verhindert werden.

In Sachen: Einäscherungs-Öfen für Konzentrationslager.

Betrifft: Neukonstruktion.

SONDERAKTEN

Der starke Bedarf an Einäscherungs-Öfen für Konzentrationslager - der in letzter Zeit besonders deutlich für Auschwitz in Erscheinung getreten ist, und der laut Bericht des Herrn Prüfer wieder zu einer Bestellung auf 7 Stück Dreimuffel-Öfen führte - veranlasste mich zu einer Prüfung der Frage, ob das bisherige Ofensystem mit Muffel für obengenannte Stellen ~~ven~~ das richtige ist. Meiner Ansicht nach geht in den Muffel-Öfen die Einäscherung nicht schnell genug vor sich, um eine große Anzahl von Leichen in wünschenswert kurzer Zeit zu beseitigen. Man hilft sich also mit einer Vielzahl von Öfen bezw. Muffeln und mit einem Vollstopfen der einzelnen Muffel mit mehreren Leichen, ohne aber damit die Grundursache, nämlich die Mängel des Muffelsystemes, zu beheben.

Diese Mängel der Muffel-Öfen, die auch durch Zusammensetzung zu Vielmuffel-Öfen (Drei- bezw. Acht-Muffelöfen) und durch das gleichzeitige Belegen der einzelnen Muffeln mit mehreren Leichen nicht aufgehoben werden, sind m.E. folgende:

1). Unterbrochener Betrieb.
Jede Muffel muss in bestimmten Zeiträumen neu gefüllt, gereinigt, dann wieder gefüllt und wieder gereinigt werden, und so setzt sich das Spiel während der Dauer des Ofenbetriebes fort. Zu jedem Spiel muss jedesmal die vordere Einführtür geöffnet und die Leichen müssen von vorn durch diese Tür in die Muffel eingeschoben werden. Während der Dauer dieser Handlung zieht kalte Luft in die Öfen ein, kühlt die Muffel ab, was die Haltbarkeit dieser herabsetzt, und verursacht außerdem Wärmeverluste, die jedesmal durch erhöhten Brennstoff-Aufwand ersetzt werden müssen.

2). Schwierigkeiten der Einführung.
Es ist jedenfalls eine harte und unangenehme Arbeit, die Leichen in der Längs-

b.w.

Eigener Brief. **Formular 4**

Document 242: Letter from Engineer Fritz Sander of J.A. Topf & Söhne from 14 September 1942. Source: www.topfundsoehne.de.

richtung der Muffel in diese einzuführen, namentlich wenn in die Muffel immer gleichzeitig mehrere Leichen hineingepackt werden müssen. Auch werden dabei Beschädigungen des doch immerhin empfindlichen Muffelmauerwerkes auf die Dauer nicht zu vermeiden sein.

3). Großer Platzbedarf der Mehrmuffel-Öfen.
In bezug auf die Grundfläche nehmen die Mehrmuffel-Öfen ziemlichen Raum ein und bedingen zu ihrem Aufbau eine erhebliche Materialmenge. Außerdem müssen die zu verbrennenden Leichen jedesmal vor die Einführöffnung der betr. Muffel transportiert, also auf eine ganze Anzahl solcher Stellen verteilt werden. Solche sind somit über die gesamte Grundfläche des Einäscherungsraumes verstreut. Das Gleiche gilt bedingt auch für das Heizmaterial.

Zur Behebung vorgenannter Nachteile und als meiner Ansicht nach ideale Lösung bezüglich Bauart eines Einäscherungs-Ofens für die Zwecke eines Konzentrationslagers sehe ich einen solchen mit kontinuierlicher Beschickung und für ebensolchen Betrieb an. Vorteilhaft wäre z.B. ein derartiger Ofen in Form eines Tunnel-Ofens. Dabei würden die einzuäschernden Leichen am vorderen Ende eines langgestreckten, inwendig beheizten Tunnels auf eine bewegte Auflage-Vorrichtung aufgegeben werden, die sich längs durch den Ofen hindurchzieht, die Leichen durch eine Anheizzone in die Verbrennungszone führt und am Schluss die Asche austrägt. Demgegenüber steht aber die oft erwiesene Unmöglichkeit, irgendwelche Eisenteile auf die Dauer im Feuer beweglich zu erhalten, auch wenn, wie im vorliegenden Falle, die bewegten Teile oben naturgemäß mit Schamotte verkleidet würden. Außerdem wäre ein ständiger Kraftbedarf zum Bewegen der beispielsweise als Doppelkette ausgebildeten bewegten Auflage-Vorrichtung notwendig. Schließlich wäre die Anordnung der Rauchgaszüge usw. kompliziert, sodass aus allen vorgenannten Gründen diese Anordnung ausscheiden würde.

Wenn also ein Ofen kontinuierlich beschickt und betrieben werden soll, so muss - um im Feuer zu bewegende Konstruktionsteile zu vermeiden - die Bewegung der eingeführten Leichen innerhalb des Ofens selbsttätig durch die natürliche Schwerkraft erfolgen. Die Leichen müssen also auf entsprechend geneigten und geformten Unterlagen in den Ofen hinein und durch diesen hindurchgleiten, auf diesem Wege in's Brennen geraten und schließlich an einer geeigneten Stelle ausbrennen und veraschen. Ich habe einen entsprechenden Entwurf ausgearbeitet, der 3 Gleitbahnen vorsieht, die zickzackartig aufeinander folgen und rostartig ausgebildet sind. Oben, am Anfang der obersten

Bericht von Herrn Sander

betr.: Einäscherungs-Öfen für Konzentrationslager.

Gleitbahn befindet sich eine genügend weite Einführöffnung, die normalerweise stets durch eine geeignete, nach innen ausweichende Klapptür geschlossen ist. Durch diese Einführöffnung werden die einzuäschernden Leichen so aufgegeben, dass sie quer zur Längsrichtung des Körpers auf die erste Gleitbahn gelangen. Um die Quereinführung zu ermöglichen, ist der Ofen mit 1,9 m lichter Breite vorgesehen. Am Ende der ersten Gleitbahn schließt sich an der Umkehr, in entgegengesetzter Neigung, die zweite Gleitbahn an, an dieser die dritte und am Fuße letzterer ist der wagerechtliegende Ausbrennrost vorgesehen. Vor diesem wird die Feuerung angeordnet, die entweder als Planrost-, Treppenrost-, Generator-, Öl- oder sonstige Feuerung ausgeführt werden kann, je nach dem Brennmaterial, welches verheizt werden muss. Die Flammen- bezw. Heizgas-Führung ist so gedacht, dass alle Gleitbahnen und sonstigen Auflagen, die ja, wie oben gesagt, rostartig ausgebildet sind, den Flammen und Rauchgasen von unten bis oben den Durchgang ermöglichen. Die Einäscherungs-Objekte sind also auf dem ganzen Weg durch den Ofen den Einwirkungen der Flammen bezw. Heizgase ausgesetzt. Ebenfalls am oberen Ende des Ofens, der Einführöffnung gegenüber, liegt die Austrittsöffnung für die abzuleitenden Rauchgase, die dort in geeigneter Weise in den Schornstein eintreten können.

Durch entsprechend angeordnete Nachstoßöffnungen kann bei einem eventuellen Festbrennen oder Festklemmen der Einäscherungs-Objekte von außen nachgeholfen werden. Asche, die beim Verbrennungs-Vorgang innerhalb des Ofens anfällt, soll, soweit möglich, durch die Öffnungen der Gleitbahnen und sonstigen Auflager nach unten durchfallen. Solche Asche, die sich unterwegs eventuel auf der Rückseite durchbrochener Gewölbe und sonstwo absetzt, soll durch entsprechende Asche-Reinigungsöffnungen nach außen abgezogen werden. Die Hauptasche sammelt sich unter dem Ausbrennrost in einer entsprechend großen Aschekammer, die an ihrer Oberfläche auch dauernd der Einwirkung der Heizgase unterliegt, sodass auch noch nicht ausgebrannte Reste der Einäscherungs-Objekte in diesem Ascheraum noch nach- und ausbrennen können.

b.w.

Eigener Brief
Formular 5

Document 242: continued.

Ein Ofen dieser Bauart würde also ununterbrochen arbeiten, d.h., die zu verbrennenden Leichen würden oben - ohne Störung des Verbrennungs-Vorganges - in entsprechenden zeitlichen Zwischenräumen aufgegeben, auf dem Weg durch den Ofen zünden, brennen, ausbrennen und veraschen, und in Form ausgebrannter Asche in der Aschekammer unter dem Ausbrennrost landen. Dabei bin ich mir vollkommen klar darüber, dass ein solcher Ofen als reine Vernichtungs-Vorrichtung anzusehen ist, dass also die Begriffe Pietät, Aschetrennung sowie jegliche Gefühlsmomente vollständig ausgeschaltet werden müssen. All das ist aber wohl auch schon jetzt bei dem Betriebe mit zahlreichen Muffel-Öfen der Fall. Es liegen eben in den KZ-Lagern besondere kriegsbedingte Umstände vor, die zu derartigen Verfahren zwingen.

Ein erschwerender Umstand beim Betrieb der von mir vorgeschlagenen Neukonstruktion gegenüber den bisherigen Muffel-Öfen liegt lediglich darin, dass der neue Ofen höher bauen würde, und dass die Einäscherungs-Objekte infolgedessen erst auf eine gewisse Höhe gebracht werden müssten. Ich betrachte diesen Umstand jedoch nicht als so schwerwiegend, ~~d~~ um deswegen die Neukonstruktion nicht vorzuschlagen, weil sich das Hochbringen der Leichen jedenfalls durch eine entsprechende Vorrichtung - entweder einen Aufzug einfachster Konstruktion oder eine schiefe Ebene - ausgleichen lässt und in keinem Verhältnis zu den zu erwartenden Vorteilen des neuen Ofens steht.

Eine weitere Erschwernis, die allerdings nur bei den ersten Ausführungen eintreten ~~wird~~, ist die, dass eine ganze Anzahl Schamotteformsteine und demzufolge Modelle für solche gebraucht werden, weil selbstverständlich im Innern des Ofens Eisenteile soviel als irgend tunlich vermieden werden müssen. Vorläufig habe ich lediglich oben, im kühleren Teil des Ofen-Innern, neben einigen Quer-Formeisen, einen schweren gusseisernen Hohlbalken als Stütze für ein Gewölbe vorgesehen. Auch dieser kann aber voraussichtlich noch durch eine Formstein-Konstruktion ersetzt werden. Der sonstige Aufwand an Eisen ist nicht erheblich und beschränkt sich auf gusseiserne Armaturen und eine in Stahlkonstruktion auszuführende Einführ-Vorrichtung, sodass für letztere neue Modelle nicht angefertigt werden brauchen. Die erforderliche kräftige Mauerwerksverankerung muss natürlich auch bei diesem Ofen vorgesehen werden.

Herr Prüfer, mit dem ich über die Angelegenheit bereits gesprochen habe, bezweifelt, dass die Leichen selbsttätig durch den Ofen gleiten, weil nach seinen Beobachtungen an normalen Einäscherungs-Öfen in Krematorien angebrannte Leichenteile selbst auf stark

betr.: Einäscherungs-Öfen für Konzentrationslager.

geneigten Flächen zum Anbacken neigen. Ich kann diese Befürchtung nicht teilen, soweit solche aber zurecht besteht, könnte sie sicher durch die Wahl eines anderen Rutschwinkels behoben werden. Vorläufig habe ich für alle 3 Gleitbahnen eine Neigung von 35 Grad gegen die Wagerechte vorgesehen, weil erfahrungsgemäß bei diesem Rutschwinkel auch schwieriges Brennmaterial selbst rutscht. Außerdem ist ja zu beachten, dass im Maße der fortschreitenden Verbrennung den durch den Ofen gleitenden Leichen immer an dem unteren Ende der Gleitbahn die Stütze entzogen wird. Das Schwergewicht liegt somit immer am oberen Teil der Gleitbahn und drückt die auf dieser lagernde Schicht von oben her nach.

Mit Rücksicht auf die eingangs gemachten Darlegungen ist anzunehmen, dass die infragekommenden Behördenstellen auch andere Ofenbaufirmen wegen Lieferung gut und schnell arbeitender Einäscherungs-Öfen in Bewegung setzen. Auch bei diesen wird daher die Frage nach der günstigsten Bauart derartiger Öfen für vorgenannte Zwecke geprüft werden. Ich muss also voraussetzen, dass diese Frage jetzt allseitig aufgerollt wird, und dass daher auch in anderen Ofenbaufirmen Gedanken für neue Bauarten derartiger Öfen auftauchen. Aus diesem Grunde halte ich es für dringend notwendig, meinen Vorschlag zum Patent anzumelden, damit wir uns die Priorität sichern.

Außerdem halte ich es für wünschenswert, die Neukonstruktion einmal gründlich durchzuarbeiten, da sich dabei sicher noch mancher Vorteil herausholen lässt. Z.B. könnte ein derartiger Ofen auch als Doppel-Ofen ausgebildet werden, mit der Feuerung an beiden Enden und dem oder den Schornsteinen in der Mitte. Will man auf die anerkannten verbrennungstechnischen Vorzüge der Muffel nicht verzichten, so kann der Raum über dem Ausbrennrost auch als Muffel ausgebildet werden. Diese würde dann an einer Längsseite offen sein und durch letztere von der untersten Gleitbahn her beschickt werden. Die Muffel würde dann für eine Beschleunigung des Ausbrandes sorgen und damit zu einem noch schnelleren Durchlass durch den Gesamt-Ofen mit beitragen.

Betr.: Krematorium VI.
Bezug: - ohne -
Anlg.: 1 Klammer.

An den
Lagerkommandanten
ᛋᛋ - Obersturmbannführer H ö s s
A u s c h w i t z O/S!

Unter Bezugnahme auf die Unterredung des Unterfertigten und den Ingenieur P r ü f e r von der Firma Topf und Söhne am 29.1.43 wurde die Planung eines 6.Krematoriums (eine offene Verbrennungskammer mit den Ausmaßen von 48,75 x 3,76 m) in Erwägung gezogen. Die Zentralbauleitung hatte daraufhin die Firma Topf und Söhne beauftragt, einen Entwurf für diese offene Verbrennungsstätte anzufertigen, der in der Anlage beigefügt wird.

Sollte der Bau dieses 6.Krematoriums durchgeführt werden, so wird gebeten, einen entsprechenden Antrag durch die Amtsgruppe D an die Amtsgruppe C zu stellen.

Bei einer eventuellen Durchführung dieser Anlage sind ausser den jetzt im Einsatz befindlichen Arbeitskräften neue Arbeitskräfte durch die Kommandantur zur Verfügung zu stellen. Es sind hierzu erforderlich:

150 Häftlingsmaurer
200 Häftlingsbauhilfsarbeiter.

Die Durchführung der Baumaßnahme ist abhängig von der Gestellung vorerwähnter Arbeitskräfte.

Der Leiter der Zentralbauleitung
der Waffen-ᛋᛋ und Polizei Auschwitz.

ᛋᛋ - Sturmbannführer.

ᛋᛋ-Ustuf.Kirschneck
Registratur (Akt Krematorium KGL BW 30)

Document 243: Letter from the head of the Central Construction Office Bischoff to the Camp Commandant Höss of 12 February 1943 regarding "Crematorium VI". APMO, BW 30/34, p. 80.

740 IV. Bd. 8. Abschn.: **Keramik und Glas.** I. Grobkeramik

Man rechnet auf 1 m³ Brennraum 300 NSt. Bei 60 m Brennkanallänge und Schornsteinzug von 3 bis 5 mm WS beträgt der tägliche Feuerfortschritt etwa 6 m.

Ofenleistung nach der Näherungsformel: $L = q\,l \cdot 300/10$.

Dabei ist L Tagesleistung in NSt,
q Querschnitt des Brennkanals [m²],
l Länge des Brennkanals [m].

Ein langer Brennkanal beansprucht stärkeren Zug als ein kurzer. Kohlenverbrauch etwa 150 kg Steinkohlen je 1000 NSt.

Empfindliches Gut muß langsam gebrannt werden. Es ist oft zweckmäßig, abwechselnd mit einem Überschuß von sauerstoffreicher Luft (oxydierend) und mit einem Mangel an Sauerstoff (reduzierend) zu brennen. Besonders beim Brennen von Eisenschmelzklinkern ist dies wichtig, weil durch reduzierendes Brennen das schwer schmelzbare Eisenoxyd in das leicht schmelzende Eisenoxydul übergeführt wird und dieses den dunklen Metallglanz des Klinkers erzeugt.

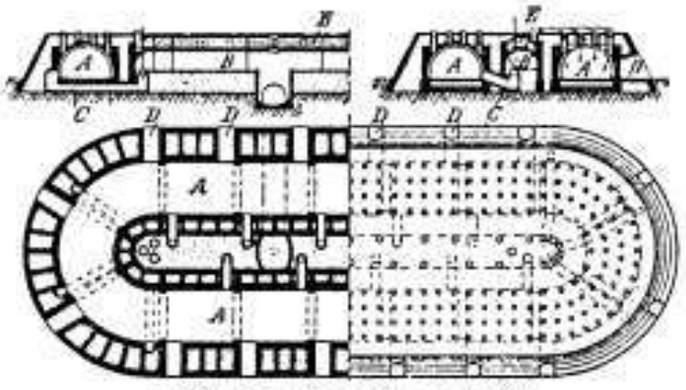

Abb. 17. Ringofen (rd. 1/600 nat. Größe).

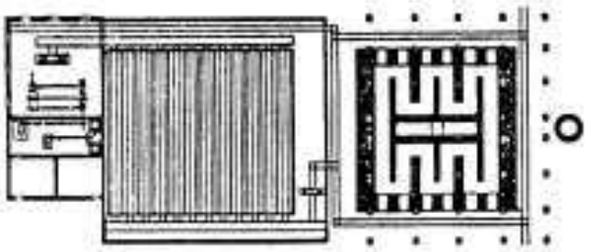

Abb. 18. Ziegelei mit Zick-Zack-Ofen und Kammertrockner (rd. 1/750 nat. Größe).

Verfärbungen. Aus den Rauchgasen können auf dem frischen und kühlen Einsatz H_2O und SO_2 niedergeschlagen und dadurch Verfärbungen erzeugt werden. Um dies zu verhindern, leitet man angewärmte, reine Luft aus den Kühlkammern des Ofens hinter dem Feuer in besonderen Schmauchkanälen (Abb. 17, *E*) an der Feuerzone des Ringofens vorbei in die vorderen, zwischen Papierschiebern abgeschlossenen Abteile. Vgl. Vormauersteine S. 742.

Zickzacköfen. Abart des Ringofens (Abb. 18), beansprucht wenig Raum und hat weniger Wärmeverluste durch Strahlung.

Man kann im Zickzackofen schnell brennen und deshalb mehr Wärme aus den Kühlkammern zu Trockenzwecken entnehmen.

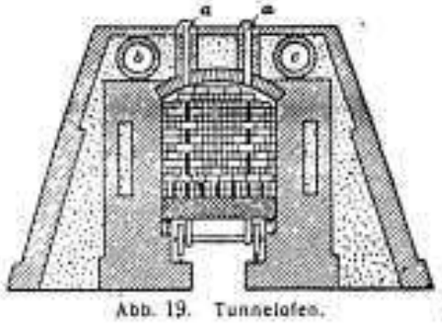

Abb. 19. Tunnelofen.

In den bisher genannten Öfen wird das Gut im Brennkanal selbst durch menschliche Arbeitskräfte eingesetzt und ausgebracht; nach jedem Brande müssen die Wände so weit abgekühlt werden, daß das Arbeiten im Ofen erträglich wird. Das bedeutet Wärmeverluste, und außerdem sind nur schwer die erforderlichen Arbeiter hierfür zu beschaffen. Beide Übel-

Kostenanschlag vom 1. 4. 43

für Auschwitz

Lfd. Nr.	Anzahl	Gegenstand der Veranschlagung
	1	gußeiserner Rauchkanalschieber mit Rollen, Drahtseil und Handwinde,
	die	erforderlichen Schürgeräte,
		Monteurstellung
		zum Bau des Ofens, einschließlich Reisekosten, Tagegelder und sozialer Abgaben.

Preis des Ofens: **RM 25 148,–**
Kennziffergewicht: 4037 kg

Während des Baues sind unseren Monteuren genügend Helfer, kostenlos für uns, zur Verfügung zu stellen. Die gesamten Mauermaterialien, wie Ziegelsteine, Sand, Kalk und Zement, müssen rechtzeitig auf der Baustelle zur Verfügung stehen; diese Materialien sind uns ebenfalls kostenlos beizustellen. Es handelt sich um:

ca. 19 000 Stück Ziegelsteine,
ca. 20 cbm Mauersand,
ca. 800 kg Zement,
ca. 6 000 kg Kalk.

Der Preis für den Ofen gilt frei Bahnwagen verladen ab Station.

BETREFF: Krematorium, Einäscherungs-Ofen, unser Angebot Nr.4o/964.

IHR ZEICHEN: –

UNSERE ABTEILUNG: D/Prf.

Wir nehmen Bezug auf die Unterredung zwischen Ihrem sehr geehrten Herrn Bauleiter B ü c h n e r und unserem Herrn Oberingenieur P r ü f e r und nahmen davon Kenntnis, daß Sie noch einen Topf-Doppelmuffel-Einäscherungs-Ofen für das Lager Gusen benötigen.

Beiliegend übersenden wir Ihnen wunschgemäß einen Kostenanschlag über:

1 koksbeheizten T o p f - Doppelmuffel-Einäscherungs-Ofen mit Druckluft-Anlage

1 T o p f - Zugverstärkungs-Anlage.

Sollten Sie die Ofenverankerung, wofür wir Ihnen eine Aufstellung mit überreichen, baueitig selbst anfertigen, so ermäßigt sich der Angebotspreis um RM 4oo.--. / Wir sind bereit, die Unterlagen zum Ofen so zu liefern, daß der Ofen in ca. 6 Wochen fertig erstellt ist.

Unser Herr Prüfer hatte Ihnen bereits mitgeteilt, daß in den vorher angebotenen Ofen stündlich zwei Leichen zur Ein-

BETRIFFT:
Ihr Schreiben vom 9.7.41
Einäscherungs-Ofen.

UNS. ZEICHEN
N/L. - Sc.

UNSERE ABTEILUNG: D IV/Frf.

Im Verfolg unseres oben angeführten Schreibens übersenden wir Ihnen wunschgemäss eine Bedienungs-Vorschrift in dreifacher Ausfertigung mit der Bitte, eine hiervon im Ofenraum an sichtbarer Stelle aufzuhängen. Die beiden anderen können Sie zu Ihren Akten nehmen.

In dem kohlebeheizten TOPF-Doppelmuffel-Einäscherungsofen können in ca. 1o Stunden 3o bis 36 Leichen zur Einäscherung gelangen. Vorstehende Anzahl kann ohne weiteres täglich zur Einäscherung kommen, ohne den Ofen zu überlasten. Es schadet auch nichts, wenn der Betrieb es erfordert, dass Tag und Nacht Einäscherungen hintereinander vorgenommen werden. Die Tatsache besteht, dass die Schamottematerialien länger halten, wenn im Ofen dauernd gleichmässige Temperatur herrscht.

Im Jahre 1943 wurden im gleichen Ofen in 10 Stunden bis zu 300 Leichen verbrannt.

Wir hoffen, mit Vorstehendem bestens gedient zu haben und empfehlen uns Ihnen inzwischen.

Heil Hitler!

TOPF

An J. A. TOPF & SÖHNE Erfurt, den 8.9.42.

Abteilung D IV.

Unser Zeichen: D IV/Prf./hes.
In Sachen: Reichsführer SS, Berlin-Lichterfelde-West.
Betrifft: Krematorium-Auschwitz.
Vertraulich! Geheim!

SONDERAKTEN

8.9.42 Herr Obersturmführer Krone ruft an und erklärt, dass er zum Brigadeführer Kämmer bestellt sei und über seine Besichtigung des Krematoriums in Auschwitz, von der er gestern zurückgekehrt sei, zu berichten habe. Aus der Anlage in Auschwitz wäre er nicht klug geworden und wollte sich deshalb genau informieren, wieviel Muffeln dort zur Zeit in Betrieb seien, und wieviel Öfen mit Muffeln wir zur Zeit dort bauen und noch liefern.

Ich gab an, dass zur Zeit 3 Stück Zweimuffel-Öfen mit einer Leistung von 250 je Tag in Betrieb seien. Ferner wären jetzt in Bau 5 Stück Dreimuffel-

Öfen mit einer täglichen Leistung von 800. Zum Versand kämen heute und in den nächsten Tagen die von Mogilew abgezweigten 2 Stück Achtmuffel-Öfen mit einer Leistung von je 800 täglich.

Herr K. erklärte, dass diese Anzahl von Muffeln noch nicht ausreichend sei; wir sollen noch weitere Öfen schnellstens liefern.

Es ist daher zweckmäßig, dass ich am Donnerstag Vormittag nach Berlin käme, um mit Herrn K. über weitere Lieferungen zu sprechen. Ich soll Unterlagen über Auschwitz mitbringen, damit nun endgültig einmal die dringenden Rufe verstummen würden.

Den Besuch für Donnerstag habe ich zugesagt.

Betrifft: Krematorium

In Ergänzung unseres heutigen Berichtes über den Betrieb der Einäscherungsöfen im Konz.-Lagers Lublin, lassen wir Sie noch wissen, dass der Brennstoffbedarf beim Betrieb stationärer Krematorien bei guter Betriebsbeobachtung auf einen sehr geringen Verbrauch zurückgebracht werden kann; denn das Verbrennungsgut selbst trägt ja im wesentlichen durch seine gute Brennbarkeit zu einer Brennstoffersparnis bei, wenn die Temperatur im Verbrennungsraum des Krematoriums sich um 700 °bewgt.

Für die Bereitstellung von Brennmaterial für eine bestimmte Heizperiode kann man annehmen, dass zum Erhitzen eines Ofens 50 kg. Koks und für jede Einäscherung 25 kg Koks gebraucht werden. Daraus ergibt sich ein Tagesbedarf von 10 Einäscherungen gleich rund 300 kg.- Es ist dabei unbenommen, ob man nur mit Koks arbeitet, oder mit einem Gemisch von Koks und Steinkohle. Im letzten Falle wird man 150 kg zu 150 kg verfahren. Mit einer gleichen Brennstoffmenge von 300 kg für einen Tagesbetrieb lassen sich auch ohne weiteres ca 20 Einäscherungen erledigen, wenn man von Einzeleinführungen Abstand nimmt.

In der Erwartung, dass Ihnen mit unserem Heutigen gedient ist, zeichnen wir mit

Heil Hitler
Hans K o r i G.m.b.H.

10.Juli 1942

Bftgb.Nr.70225/42/Er/Ha. **Einschreiben**

Betr.: Neubau eines Krematorium für das K.L. Stutthof
Bezug: Dort. Schreiben vom 15.6.42 Tgb.Nr. 281/42/Neu./D.11
Anlg.: 8 Pläne

An die

Bauleitung der Waffen-SS
und Polizei

S t u t t h o f - D a n z i g

In der Anlage werden die Pläne für ein Krematorium für 30.000 Häftlinge überreicht. Die Anlage ist mit 5 Stück Dreimuffel-Verbrennungsöfen ausgerüstet. Nach Angabe der Firma Topf & Söhne Erfurt dauert eine Verbrennung ca. 1/2 Stunde. Die Keller wurden deshalb gehoben, da an der Baustelle ein hoher Grundwasserstand ist.

Bezüglich der technischen Einrichtungen wird anheim gestellt, sich mit der Firma Topf & Söhne Erfurt in Verbindung zu setzen.

Der Leiter der Zentralbauleitung
der Waffen-SS und Polizei Auschwitz

SS-Hauptsturmführer (S)

Tgb.: 24 757/43/J/Ln Auschwitz, am 17.3.1943

Aktenvermerk

Betr.: Schätzung des Koksverbrauches für Krematorium II KGL nach Angaben der Fa. Topf u. Söhne (Erbauer der Öfen) vom 11.3.43.

10 Feuerungen = 350 kg/stdl.

in 12 Std. = 12 . 350 = 4 200 kg. 2 Krematorien demnach 8 400 kg.

Bei Dauerbetrieb vermindert sich diese Menge wesentlich, sodass mit 2/3 der Menge gerechnet werden kann. Für Krematorium II u. III demnach Verbrauch in 12 Stunden = $\frac{350 \cdot 12}{3} \cdot 2 = 2800 \cdot 2 = \frac{5600}{kg.}$

- - - - - - - - - - - - -

Krematorium IV + V:

mit je 4 Feuerungen = 8 Feuerungen zusammen =

$\frac{35 \cdot 4 \cdot 12}{3} \cdot 2 = 1120 \cdot 2 = 2240$ kg in 12 Stunden (1 Tagesbetr.)

- - - - - - - - - - - - -

Krematorium	II	= 2 800 kg
"	III	= 2 800 "
"	IV	= 1 120 "
"	V	= 1 120 "
	sus.	= 7 840 kg in 12 Stdt.(1 Tagesbetr.)

- - - - - - - - - - - - -

Dies sind Spitzenleistungen! Ein Jahresbedarf lässt sich nicht angeben, da vorher nicht bekannt ist, wieviel Stunden bezw. Tage geheizt werden muss.

TYPENBEZEICHNUNG UND VERWENDUNGSZWECKE DER KORI-ÖFEN

KORI-Öfen **Typus I Ia II IIa IV V IX X** finden Verwendung

für kleine, mittlere und große Krankenhäuser, Kliniken, Lazarette, Spitäler, Ambulanzen, medizinische, hygienische und wissenschaftliche Institute, Desinfektionsanstalten sowie für Heil-, Pflege- und Irrenanstalten, Seuchenstationen, Frauenkliniken und Sanatorien

zum Verbrennen von Krankenhausabfällen aller Art, Verbandstoffen, Sputum, Operations- und Amputationsresten, Leichenteilen, Versuchstieren sowie Küchenabfällen, Speiseresten, Blumen, Kehricht und Gartenabraum.

KORI-Öfen **Typus I Ia III IIIa V X** finden Verwendung

für kleine, mittlere u. große Schlachthöfe, Viehhöfe, Veterinärinstitute, tierärztliche Hochschulen, Gestüte, Zoologische Gärten, Abdeckereien, Fischereihäfen, Konservenfabriken

zum Verbrennen von Schlachthausabfällen aller Art, Konfiskaten, Groß- und Kleintierkadavern, Borsten und sonstigen tierischen Rückständen, auch breiigen und flüssigen Abgängen, sowie Stallmist und Dung.

KORI-Öfen **Typus IV V XI XII** finden Verwendung

für gewerbliche Großbetriebe, Waren- und Kaufhäuser, Lebensmittelgeschäfte, Konsumvereine, Büro-, Bank- und Geschäftshäuser, Behörden, Zollämter, Fabrik- und industrielle Betriebe, Hotels, Restaurants und Vergnügungslokale, Säle und Versammlungshallen

zum Verbrennen von Büro- und Fabrikationsabfällen der verschiedensten Art, Papier- und Packmaterial, Emballagen, trockenen und feuchten Lebensmittel- und Küchenabfällen, Kehricht, Hofabraum usw.

KORI-Öfen **Typus IV V VI VII VIII** finden Verwendung

für Markthallen und Märkte, Ausstellungshallen, Messegelände, Gefängnisse und Strafanstalten, Kasernen, Truppenübungsplätze und Barackenlager, Wohnungsblocks und Siedlungen, Flughäfen, Bahnhöfe, Hafenanlagen, Fischereihäfen, Kläranlagen, Friedhöfe

zum Verbrennen von trockenem, feuchtem und gemischtem Abfallmaterial, wie verdorbene Fleischabfälle, Fische, Obst und Gemüsereste, wie auch Küchenabfälle, Kehricht und sonstiger Abraum, wie z. B. vertrocknete Kränze und Blumen auf Friedhöfen, Papierabfälle und Emballagen, Hausmüll aller Art.

KORI-Öfen **Typus XI XII** finden Verwendung

als Klein-Müllverbrennungsöfen für Büros, Gesandtschaften, Finanzämter sowie für Einzelhaushaltungen

zum Verbrennen von Papierabfällen, Akten, Zeichnungen und Dokumenten sowie von Küchen- und sonstigen Hausabfällen. Alles soweit unverwertbar.

H. KORI G. m. b. H. BERLIN

Telegr.-Adr.: Kori-Berlin 57 **W 57, Dennewitzstraße 35** *Fernspr.: B 2 Lützow 2430*

Technisches Büro und Fabrik für Entwurf und vollständige Lieferung von

Verbrennungsöfen für Abfälle aller Art

Einäscherungsöfen für Krematorien

Glüh-, Schmelz- u. Härteöfen, Kesseleinmauerungen, Schornsteinbau

Über die Notwendigkeit und Zweckmäßigkeit der Abfallverbrennung braucht heute kein Wort mehr gesagt zu werden.

Nachdem von uns im Laufe von über 40 Jahren Tausende der verschiedenartigsten Verbrennungsöfen geliefert wurden, die überall zur größten Zufriedenheit arbeiten, darf unseren Apparaten unbedingtes Vertrauen entgegengebracht werden.

Durch schnelle, sichere, einwandfreie, in Anlage und Betrieb gleich billige Beseitigung und restlose Vernichtung aller Art von Abfällen erfüllen unsere Verbrennungsöfen sowohl die Forderungen der öffentlichen Gesundheitspflege, als alle Ansprüche eines wirtschaftlichen Betriebes, der durch die Ausnutzung der Abgase für Warmwasser-Bereitungen, Bäder oder für andere Zwecke wesentlich gesteigert wird.

Unsere Verbrennungsöfen

finden daher mit größtem Vorteil Verwendung für:

1. *Medizinische, bakteriolog., hygien. u. a. wissenschaftliche Institute.*
2. *Kliniken, Lazarette, Kranken-, Irren-, Heil- und Pflegeanstalten.*
3. *Sanatorien, Bade- und Kuranstalten, Genesungsheime, Heilstätten.*
4. *Veterinär-Institute, tierärztliche und landwirtschaftliche Hochschulen.*
5. *Schlacht- und Viehhöfe, Abdeckereien, Gestüte, Serum- und ähnliche Institute.*
6. *Markthallen, Fischereihäfen, Konservenfabriken, Konsumvereine und dergleichen.*
7. *Friedhöfe, Desinfektionsanstalten, Kläranlagen, Seuchenstationen.*
8. *Kasernen, Festungen, Truppenübungsplätze, Barackenlager, Werften.*
9. *Gefängnisse, Straf-, Erziehungs- und andere geschlossene Anstalten.*
10. *Kauf-, Waren- und Geschäftshäuser, Bank-, Büro- und Verwaltungsgebäude.*
11. *Fabriken, Werkstätten, industrielle Anlagen, Hüttenwerke usw.*
12. *Hotels, Restaurants, Vergnügungslokale, Theater, Zoologische Gärten.*
13. *Meßgelände, Ausstellungshallen, Bahnhöfe, Hafenanlagen, Märkte und dergl. sowie für alle möglichen anderen Zwecke.*

Im ganzen haben wir bisher etwa 3500 Verbrennungsöfen geliefert.

Überall, wo regelmäßig Abfälle entstehen, die wegen ihrer gesundheitsgefährlichen Eigenschaften eine schnelle Vernichtung verlangen oder deren regelmäßige Abfuhr und anderweitige Unterbringung laufende Ausgaben verursacht, bilden unsere Verbrennungsöfen das beste Hilfsmittel, allen Ansprüchen der Hygiene zu genügen. Dabei erweist sich die Verbrennung auch wirtschaftlich als das billigste Verfahren, weil die Anlagekosten der Öfen gering sind, die Bedienung einfach und der Kohlenverbrauch so mäßig ist (bzw. ganz fortfällt), daß die Unterhaltungs- und Betriebsausgaben gar keine Rolle spielen.

Nachstehend sind einige der gebräuchlichsten Ofentypen kurz erwähnt und besprochen. Ausführliche Drucksachen und Kostenanschläge stehen gern zur Verfügung.

Sygn. VI-9a, vol. 1

Document 267: Promotion leaflet by the H. KORI COMPANY, Berlin 1927, regarding incinerators for all kinds of refuse. Source: APMM, sygn. VI-9a, vol. 1.

Typen IV, IV a, V u. VI. Öfen mit doppelten Verbrennungskammern.

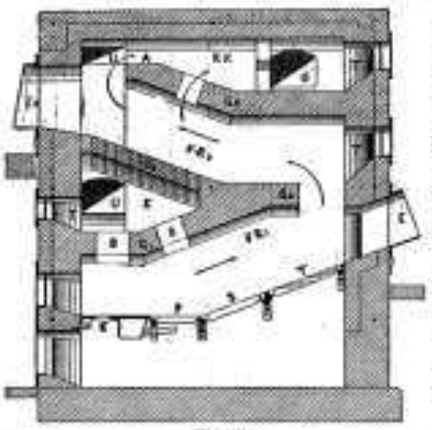

Fig. 6

In Pflegeanstalten, Heilstätten usw. handelt es sich in der Hauptsache um die Vernichtung von Kehricht, Müll und Wirtschaftsabfällen, doch kommen durch den Krankenhausbetrieb auch Verbandstoffe, Amputationsreste, Leichenteile usw. in Frage. Will man diese Abfälle getrennt vom Müll verbrennen, so erhält der Ofen die aus Fig. 6 ersichtliche Ausführung mit zwei übereinander liegenden Kammern. Meistens wird diese Ausführungsform auch dort verwendet, wo gleichzeitig feuchtes und trockenes Material verbrannt werden muß. Die zwei Einwürfe E_1 und E_2 können auch an derselben Stirnseite des Ofens liegen. Eine Nebenfeuerung zur Nachverbrennung der Rauchgase wird seitlich am Ofen angebaut, der sich konstruktiv den jeweiligen Bedürfnissen anpassen läßt.

Bei Type IV für Waren- und Geschäftshäuser, Banken, Fabriken usw. fällt meist die obere Verbrennungskammer fort. Dafür werden häufig Heißwasserspiralen eingebaut.

Bei Type VI für Markthallen und dgl. wird die Sohle der unteren Kammer mit durchbrochenem Gewölbe versehen.

Type VII/VIII. Ofen für Desinfektionsanstalten, Friedhöfe usw.

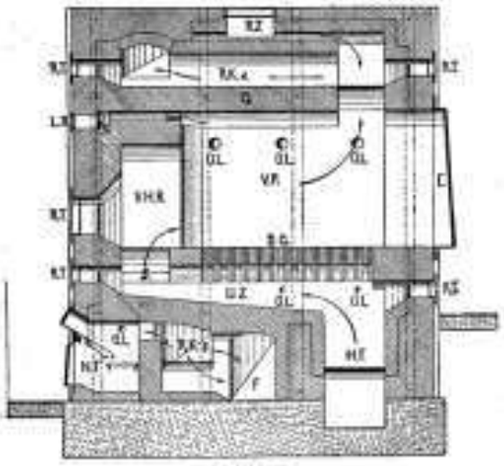

Fig. 7

Wie Fig. 7 zeigt, besteht der Verbrennungsraum aus einer Kammer mit horizontaler Sohle mit durchbrochenen Schamottesteinen *DG*. Darunter liegt die Hauptfeuerung *HF*, deren Flamme durch den Unterzug *UZ* und die Schlitze des Gewölbes *DG* hindurchzieht und die Abfälle von allen Seiten in Feuer hüllt. Eine reichliche Zuleitung hocherhitzter Verbrennungsluft erfolgt durch die Oberluftöffnungen *OL*, die alle sich bildenden Gase und Dämpfe verzehrt. — In dem Rauchabzugskanal RK_1 und den anschließenden senkrechten Zügen ist den abziehenden Gasen Zeit gelassen, vollkommen auszubrennen. Unten vereinigen sich die Züge im Rauchkanal RK_2. In der hinteren Stirnseite des Ofens ist die Nebenfeuerung *NF* eingebaut zur Nachverbrennung der Gase. Hinterlassen die Rückstände, wie z. B. bei Friedhofmüll (Type VIII), zusammengeballten, glühenden Bindedraht, so wird eine Kühlkammer angeordnet.

Type IX. Verbrennungsöfen für Wohngebäude und Kleinbetriebe.

Fig. 8

Das Bestreben, Hausmüll und Kehricht auf dem Wege der Verbrennung zu beseitigen, wie es in England seit langen Jahren geschieht, hat auch auf dem Kontinent zum Bau zentraler Müllverbrennungs-Anstalten geführt. Allerdings haben sich diese nicht überall bewährt, weil die Beschaffenheit des Mülls sehr verschieden, und die Nachfrage nach den Schlackenrückständen gering ist. Auch hängt die Rentabilität davon ab, welche Unkosten die Abfuhr bisher verursachte. Diese Umstände trugen dazu bei, daß manche Müllverbrennungs-Anstalten stillgelegt wurden.

Um aber die hygienischen Vorteile der Verbrennung nicht preiszugeben und die Abfuhr und Unterbringung des Mülls zu entlasten, könnten — abgesehen von all den auf Seite 1 erwähnten Fällen — auch in Wohn- und Einzelhäusern, vor allem mit Zentralheizung, kleine Müllverbrennungsöfen aufgestellt werden. Es würde sich dann die Abfuhr auf Asche und Schlacke der Küchen, Zentralheizung und des Verbrennungsofens, sowie der unverbrennlichen Abfälle beschränken und so zur Entlastung der allgemeinen Abfuhr wesentlich beitragen.

Einen solchen kleinen Verbrennungsofen für Einzelhäuser stellt Fig. 8 dar, der in verschiedenen Größen, bis 300 Liter Fassungsraum, geliefert wird. — Für größere Gebäude käme Type IV in Frage.

X. Verbrennungsöfen mit Gasbetrieb.

Während in der Regel für den Betrieb der Verbrennungsöfen (sofern überhaupt ein Brennstoffzusatz nötig ist) feste Brennstoffe Verwendung finden, werden die Verbrennungsöfen Type IX sehr vielfach auch für Leuchtgasbeheizung geliefert, wegen der reinlichen und bequemen Handhabung und der steten Betriebsbereitschaft. Aber auch größere Öfen haben wir, und zwar mit bestem Erfolge, mit Gasfeuerung versehen, nur ist dann die Bauart den veränderten Anforderungen anzupassen. Jedenfalls bietet der Gasbetrieb in vielen Fällen Vorteile, die sich allmählich noch weiter ausgestalten lassen.

Abteilung Heizung

Sammelheizung, Warmwasserbereitung
Alle Heizungsarten von der Stockwerksheizung bis zur Pumpen-Warmwasser- und Fernheizung. Heizungsanlagen für Siedlungen, Villen, Wohn- und Geschäftshäuser, Hotels, Industriebauten und öffentliche Gebäude aller Art. Erste Empfehlungen bei Behörden, Architekten und Privaten.

Luftheizungs-Anlagen
insbesondere Großraum-Heizungen für Hallen, Sport- und Festräume, Säle, Werkstätten, Garagen usw. Hersteller der Kori-Kalorifere (Luftheizapparate, s. Bild 1), verschiedene Bauarten und Größen für alle Zwecke und Größenverhältnisse (u. a. Stadt- und Festhalle Güstrow).
Besondere Vorzüge: Hohe Wärmeleistung bei geringem Platzbedarf; kräftige Bauart (schamotteausgemauerter Guß), daher lange Lebensdauer; weitgehende Heizgasausnutzung, daher mäßiger Brennstoffverbrauch.

Kirchenheizungen
Führendes Unternehmen auf diesem Sondergebiet. Viele Hunderte von Anlagen jeden Umfanges im In- und Ausland, in Form von Kalorifer- oder Dampf-Luftheizung mit oder ohne Ventilatorbetrieb, Niederdruck-Dampfheizung oder Einzelofenheizung. Vorschläge und Beratung kostenlos.

Einzelöfen
Kori-Öfen jeder Art und Größe mit und ohne Mantel oder eingemauert. Bewährt für Schulen, kleine Kirchen, Kasernen, Lazarette, Gefängnisse, Werkstätten, Fabriken, Turnhallen, Versammlungssäle, Baracken usw.

Lüftungs- und Trockeneinrichtungen — Abwärme-Verwertung
Zubehörteile
aller Art für Heizungs- und Lüftungsanlagen: Kessel, Heizkörper, Warmwasserspeicher, Dampfwasserableiter, Ventile, Hähne, Pumpen, Gitter usw.

Abteilung Feuerung

Müll- und Abfall-Verbrennungsöfen (Bild 2)
Der bewährte Kori-Ofen ist das Hilfsmittel für rasche, billige und gesundheitsunschädliche Beseitigung aller denkbaren Abfälle. Wirtschaftlichkeit durch Ersparnis der Abfuhr sowie durch Rauchgasausnutzung für Warmwasserbereitung usw. Tausende von Öfen geliefert für:
Wissenschaftliche Anstalten, Krankenhäuser, Hotels und Gaststätten, Groß-Wohnhäuser, Bürogebäude, Fabriken, Waren- und Kaufhäuser, Konsumvereine, Kasernen, Strafanstalten, Barackenlager, Schlacht- und Viehhöfe, Abdeckereien, Markthallen, Fischereihäfen, Lagerhallen, Bahnhöfe, Ausstellungsgebäude, Friedhöfe, Kläranlagen, Entkeimungsanstalten.

Einäscherungsöfen für Feuerbestattung (Bild 3)
Reformofen Bauart Kori, bedeutende Ersparnis an Anlage- und Betriebskosten. Befeuerung mit festen Brennstoffen oder Gas. Betriebsfertige Lieferung einschl. Zubehör. Bewährte Sargeinführungs-Vorrichtungen eigener Bauart.

Industrieöfen
Glüh-, Schmelz-, Härte- und Emaillieröfen, Muffel-Öfen, Trocken-Öfen.

Kesseleinmauerungen und Schornsteinbau

Müllschluckanlagen (Bild 4)
Staub- und geruchsichere Verschlüsse eigener Bauart. Für die bekanntesten Großbauten Berlins und im Reiche geliefert. Besondere Schlucker für Müll, Asche, Papier und Wäsche. Verlangen Sie Vorschläge und Drucksachen.

Kundendienst
Von allen obengenannten Anlagen in 50jähriger Tätigkeit Tausende von Ausführungen zur vollen Zufriedenheit. Auch nach Übergabe Kontrolle der von uns ausgeführten Anlagen durch alten Stamm zuverlässiger Mitarbeiter. Drucksachen, Empfehlungen, Angebote, Einzelvorschläge kostenlos. Auf Wunsch unverbindlicher Ingenieurbesuch.

Sonderdruck aus dem Bauwelt-Katalog, Jahrgang 3

Einäscherungsofen System „Kori“

im

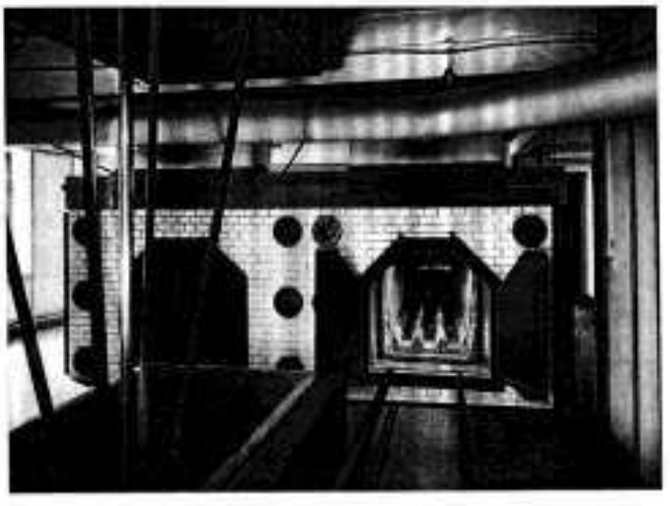
Krematorium der Stadt Hagen/Westf.

Außenansicht des Krematoriums auf dem Friedhof im Stadtteil Delstern.

Diese Einäscherungsstätte wurde 1906 als erste in Preußen erbaut und nach langem Kampf mit den Gegnern der Feuerbestattung im Jahre 1912 in Betrieb genommen.

Unterhalb der Andachtshalle befindet sich der Einäscherungsraum mit 2 Kori-Öfen, die an den links sichtbaren freistehenden Schornstein angeschlossen sind.

Ansicht der beiden Kori'schen Einäscherungsöfen.



Im Vordergrund ist die Sargversenkungseinrichtung erkennbar, mit links und rechts angeordneter Sargeinführung.

Der rechts sichtbare offene Ofen wurde im Jahre 1926 als Ersatz für einen Ofen älterer Bauart erstellt. 3 Jahre später ließ die Verwaltung auch den 2. Ofen nach System Kori umbauen.

Die Einäscherungsöfen System Kori sind in konstruktiver Beziehung seit Jahren bahnbrechend, vor allem durch wesentliche Verbesserung des Rekuperators und Wegfall des früher erforderlichen Tiefkellers, wodurch eine erhebliche Verbilligung erzielt wurde. Neuerdings werden die Kori-Öfen mit bestem Erfolg auch für Gasbetrieb eingerichtet.

Einäscherungsofen System „Kori“

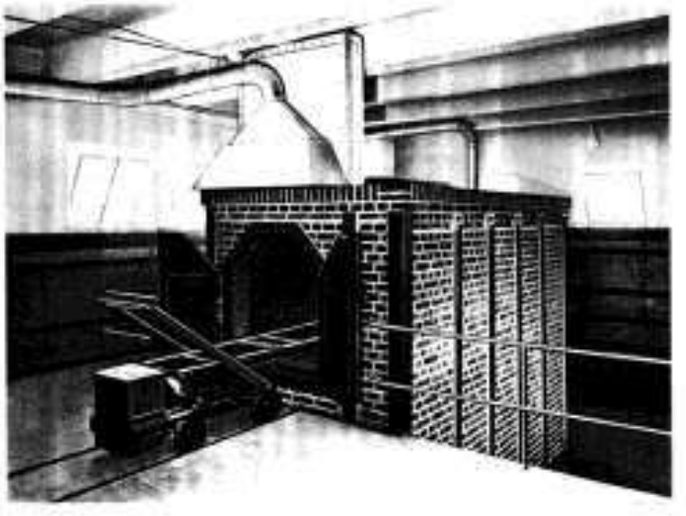
im

Krematorium der Hauptstadt Schwerin

Außenansicht des Krematoriums auf dem Schweriner Friedhof.

Dieser moderne Ziegelrohbau enthält im niedrigen Bauteil — vorn ganz rechts — die Feuerbestattungsanlage System „Kori“. Im Turmbau sind untergebracht der Schornstein für zwei Einäscherungsöfen und die Entlüftungsschächte.

Ansicht vom Kori-Einäscherungsofen mit Sargeinführungswagen.



Dieser Reformofen ist sowohl für Koksgeneratorbetrieb als auch für Gasfeuerung eingerichtet. Er besitzt einen nach neuzeitlichen Erfahrungen konstruierten Rekuperator, der gleichzeitig als Wärmespeicher dient. Der aus steilen Chamottewangen gebildete Asch-Sammelraum endigt am tiefsten Punkt auf einem Nachglührost.

Durch geschickte Gruppierung der Sargkammer mit Aschraum und Rekuperator erübrigte sich der kostspielige Tiefkeller beim Bau des Ofenraumes. Die Anordnungsfrage für die Einäscherungsöfen, von denen zunächst nur einer zur Ausführung kam, wurde räumlich und technisch vorbildlich gelöst.
(Siehe auch Grundriß- und Schnittdarstellung auf besonderem Blatt.)

Betrifft: Krematoriumsöfen

Im Verfolg der mit Ihnen gehabten mündlichen Rücksprache wegen der Beschaffung einer Einäscherungsanlage in einfacher Ausführung bringen wir Ihnen unseren Reform-Einäscherungsöfen mit Kohlenfeuerung in Vorschlag, die sich bisher in der Praxis bestens bewährt haben.- Wir bringen für das in Aussicht genommene Neuvorhaben zwei Stück Einäscherungsöfen in Vorschlag, empfehlen aber, durch Rückfrage nochmals festzustellen, ob diese beiden Oefen für den Bedarf ausreichend sind. Auch ist noch die Ofenanordnungsfrage klarzustellen, weil davon die Ausführung der Armaturteile sowie des Verankerungsgerippes abhängig ist. Die Ofenanlage ist möglichst in einem abgeschlossenen Raum unterzubringen und an einen evtl. vorhandenen Schornstein anzuschliessen.- Falls ein Aufstellungsraum bereits in Aussicht genommen ist, bitten wir Sie, uns hiervon einen Plan einzusenden, damit wir Ihnen einen brauchbaren Anordnungsvorschlag unterbreiten können. Den erforderlichen Platzbedarf der Oefen mit Bedienungs- und Schürstand können Sie aus den beigefügten Zeichnungen ersehen. Die Zeichnung - J.Nr.8998 - veranschaulicht die Anordnung von zwei Oefen, wogegen nach der Zeichnung - J.Nr.9122 - für das neuvorhaben Dachau vier Oefen zur Ausführung gekommen sind. Eine weitere Zeichnung mit der J.Nr.9080 zeigt Ihnen die Anlage Lublin mit fünf Einäscherungsöfen und zwei eingebauten Heizkammern.

Was nun die Anschaffungskosten für zwei Krematorien anbetrifft, so bieten wir Ihnen diese wie folgt an:

1) 2 Stück Reform-Einäscherungsöfen neuester Konstruktion mit gewölbter Aufgabekammer und horizontaler Aschenraumsohle einschliesslich der gesamten Armaturteile, den Einführungs-, Bedienungs- und Reinigungstüren, der Luftrosetten, den Feuerungsgarnituren für die Hauptfeuerung und dem Ausgührost, dem vollständigen Verankerungsgerippe aus kräftigen Winkeleisenschienen und Bandeisenschienen mit Unterstützungsverbänden, allen Bauunterstützungen, feuerfesten Schamotte- und Normalsteinen, Schamottemörtel, Vorsetz- und Hintermauerungssteinen, Mauermörtel und Zement sowie mit der gesamten Montage durch unseren Feuerungskonteur unter Beistellung sämtlicher Hilfsgeräte je RM.4.500,--

Falls die Aufstellung des zweiten Ofens im Anschluß an die erste Montage erfolgt, ermässigt sich der Preis für den zweiten Ofen also auf RM.4.400,--.

Document 271: Letter from the H. KORI COMPANY to Engineer Waller at Office CIII of SS WVHA dated 18 May 1943. Source: KfSD, 660/41.

- 2 -

(42) 1445

In diesem Betrag sind jedoch die Kosten für Fracht und Rollgeld der Materialien frei Verwendungsstelle sowie die Reisekosten für den Monteur und Reisegesellen sowie Landzulage nicht enthalten. Diese Kosten würden wir gesondert zum besonderen Nachweis in Anrechnung bringen.

Ebenso schliesst unser Angebot aus die baulichen Nebenarbeiten am Aufstellungsort, wie Erdaushub, Planierungsarbeit, Herstellung des Ofenaufstellungsraumes sowie die Rauchkanäle von den Oefen bis zum Schornstein und den Schornstein selbst.

Sobald die Anordnungsfrage für die Ofenanlage klargestellt worden ist, reichen wir Ihnen aber gern ein Sonderangebot über die Herstellung der Rauchkanäle nach.

Für die Einführung der Leichen in die Verbrennungskammer der Oefen bieten wir Ihnen noch zusätzlich an:

1) 2 Stück Einäscherungswagen, muldenförmig ausgebildet, mit Rollen und Handgriffen, per Stück RM.160,-- RM.320,--

2) 2 Stück Rollenböcke zur Auflagerung der Einführungswagen, per Stück RM.75,-- + 150,--
RM.470,--

Für den Effekt der zu liefernden Einäscherungsöfen sowie für deren Stabilität, auch für die Lieferung nur bester Materialien und Ausführung tadelloser Arbeiten übernehmen wir die volle Garantie.

Die Lieferung der gusseisernen Armaturen und Verankerungsteile sowie der Schamotteformsteine kann kurzfristig erfolgen, falls uns hierfür ein Wehrmachtfrachtbrief zur Verfügung gestellt wird.

Für die Lieferung der eisernen Ofenteile benötigen wir pro Ofen 1460 kg, also für zwei Oefen 2920 kg. Die Eisenanforderungsscheine hierfür finden Sie beigeschlossen.

Ihren weiteren Nachrichten gern gewärtig, empfehlen wir uns Ihnen bestens mit

Heil Hitler !

BETRIEBSVORSCHRIFT C[64]392
für die
EINÄSCHERUNG

Anzünden der Brenner:

A. Ist der Ofen noch warm und ist die Brennereinstellung seit dem letzten Betrieb nicht verändert worden, so ist neue Brennereinstellung, gleichen Brennstoff vorausgesetzt, meist nicht erforderlich.
Anzünden erfolgt in nachstehender Reihenfolge:
1.) Ventilator anlassen.
2.) Luftklappe am Brenner schliessen.
3.) Absperrventil für Öl öffnen.
4.) Brennende Lunte einführen
5.) Luftklappe öffnen.

Sobald Zündung erfolgt, Luftklappe langsam schliessen bis Flamme nicht mehr zurückschlägt, sondern ohne Rauchentwicklung gleichmässig brennt. Sollte Zündung nicht gleich erfolgen, Regulierventil bei stehenbleibendem Regulierhebel etwa ein viertel Umdrehung nach links drehen, dann wenn Brenner gezündet hat, langsam wieder nach rechts zurückdrehen. Ist der Ofen bereits warm geworden, versuchen mehr Luft zu geben, also Luftklappe mehr öffnen. Nach 5 Minuten Luftrosetten am Ofen etwa 3 cm öffnen.

B. Ist der Ofen kalt, oder war die Brennereinstellung verändert, so muss die Einstellung der Brenner folgendermassen erfolgen:
1.) Querhub auf ungefähr Mitte stellen.
2.) Ventilator anlassen.
3.) Luftklappe am Brenner schliessen.
4.) Regulierhebel ungefähr senkrecht stellen.
5.) Regulierventil oben um ca. 2 unten um ca. 1½ Umdrehungen öffnen.
6.) Brennende Lunte einführen.
7.) Absperrventil für Öl öffnen.
8.) Luftklappe ganz öffnen.

Wenn Zündung nicht sofort erfolgt, Regulierventil noch etwas aufdrehen. Nach Zünden einige Minuten später soweit schliessen bis Flamme noch gut brennt. Raucht die Flamme, dann Querhub etwas in Richtung "zu" stellen. Ist der Brenner einige Minuten im Betrieb, ist der Regulierhebel ganz nach rechts bis zum Anschlag zu stellen. Brennt die Flamme gut, dann Regulierhebel mit Regulierventil kuppeln. Eventuell Flamme nochmals mit Querhub regulieren, falls bei Grosserstellung Rauchentwicklung eintritt. Wenn Flamme stossweise erlöscht und wieder zündet (zurückschlägt), ist zuviel Luft vorhanden. Luftklappe dann soweit schliessen, bis Flamme ruhig brennt. Ist der Ofen warm geworden, kann die Luftklappe weiter geoffnet werden. Nach 5 Minuten Luftrosetten am Ofen etwa 3 cm öffnen.

DIDIER-WERKE AG

OFENBAU

Herrn
Boriwoje Palitsch

B e l g r a d
Kryeginje Zorke 94

Berlin-Wilmersdorf, Westfälische Str. 90

TE.1[1]./Hd./Sto./Ko e. 25.8.43.

Betreff: Feuerbestattungsanlage für die SS in Belgrad

Wir nehmen Bezug auf den Besuch Ihres Herrn Sohnes und die mit Ihm gehabte Rücksprache unseres Sachbearbeiters Herrn Storl. Wir nahmen davon Kenntnis, dass die Belgrader SS-Formation die Absicht hat, für ein grösseres Lager eine Feuerbestattungsanlage zu schaffen, und dass Sie beauftragt wurden, gemeinschaftlich mit einem dortigen Architekten die Anlage zu projektieren und zu erstellen.
Da Ihnen Erfahrungen für den Bau der Öfen fehlen, haben Sie die Absicht die zeichnerischen Unterlagen hierfür zu erwerben.
Wir erklären uns bereit, die Ofenzeichnung mit zugehöriger Verankerung und Armaturzeichnung anzufertigen und zwar nur um dem Gebrauch für vorstehenden Einzelfall.

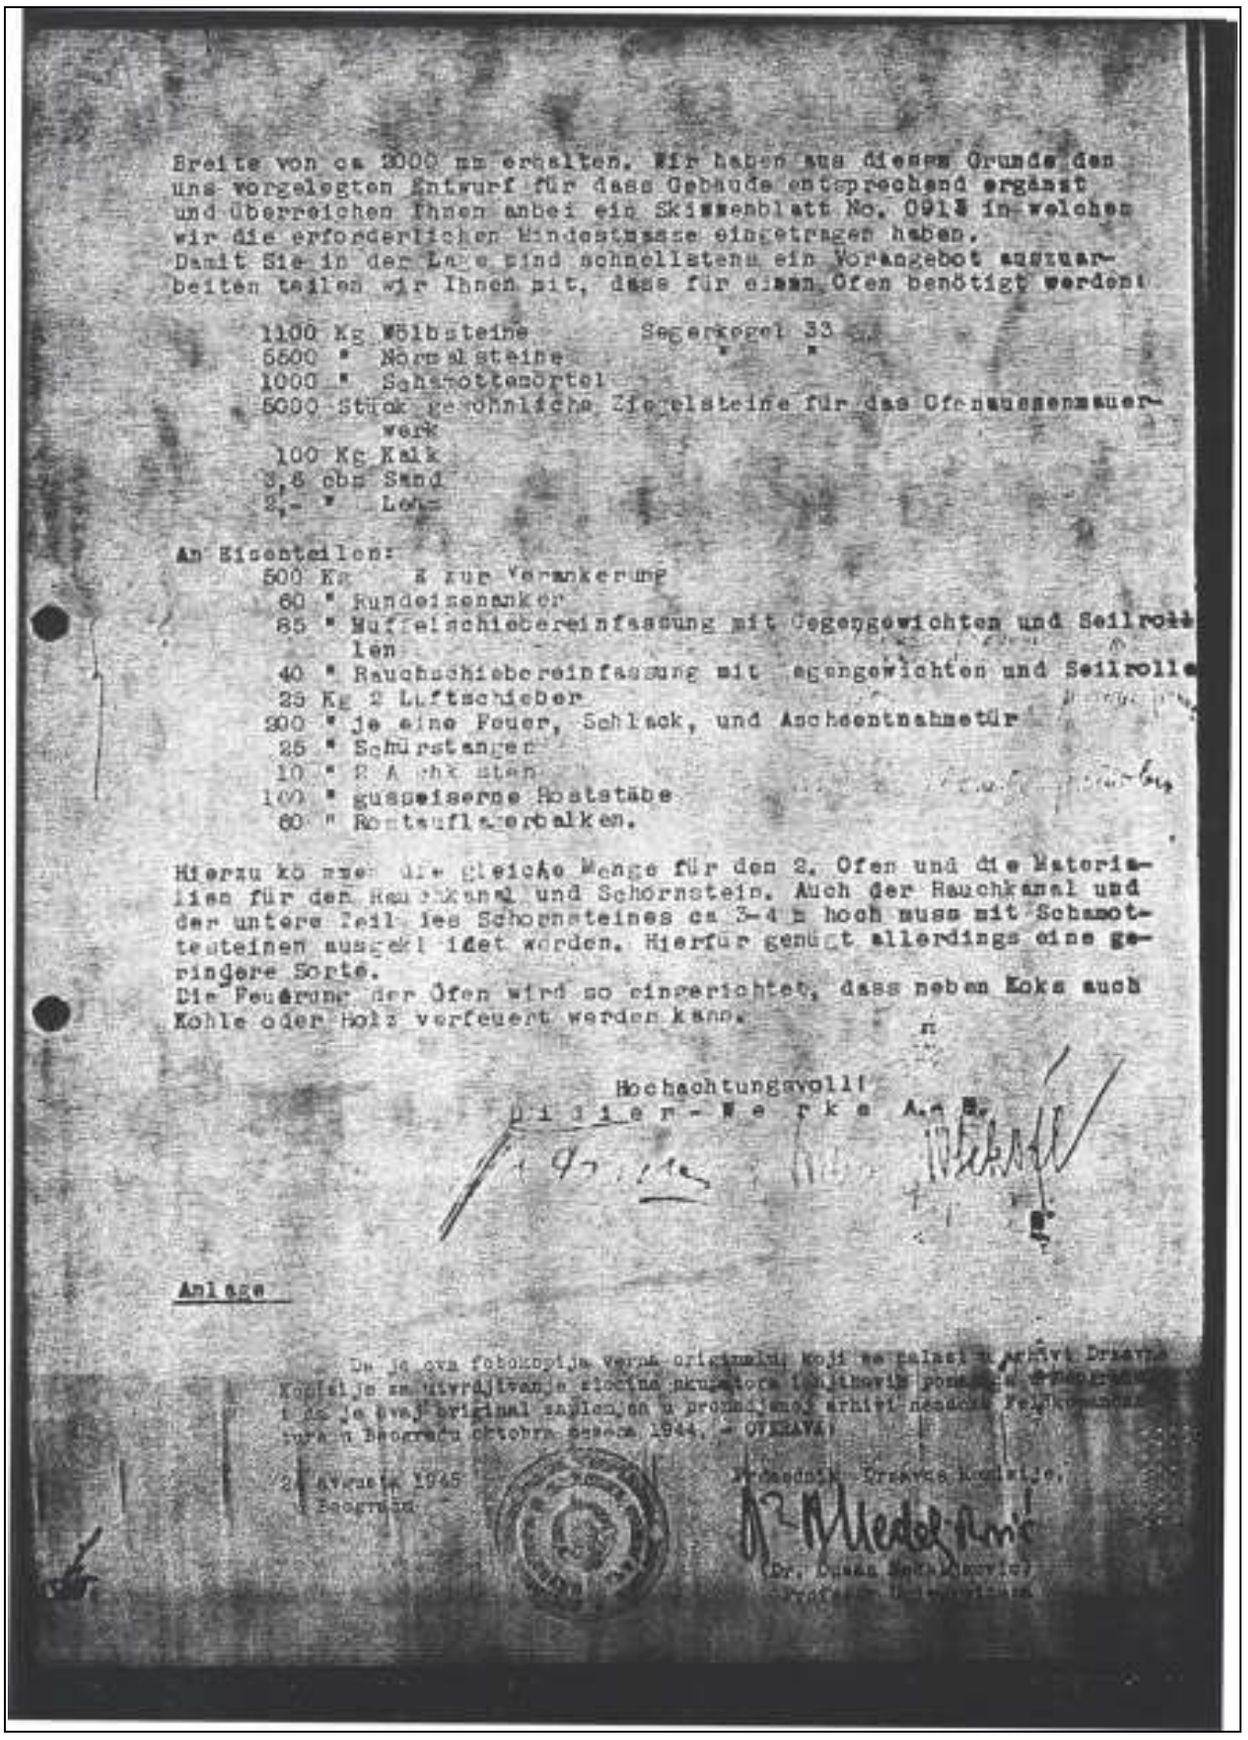
Die Kosten hierfür betragen RM. 600.-

Zahlbar je zur Hälfte bei Auftragserteilung und bei Bekanntgabe der Fertigstellung der Zeichnungen.
Bei Durcharbeitung der Ofenanlage wird besonders darauf geachtet, dass sich der innere Ausbau unter Vermeidung von besonderen Formsteinen aus normalen Schamottesteinen herstellen lässt, damit ein baldiger Aufbau der Anlage durchführbar ist. Auch die Eisenteile werden vom gleichen Gesichtspunkt aus bearbeitet.
Für das Einführen der Leichen in den Ofen, schlagen wir eine auf 2 Rollen laufende einfache Rohrgabel vor.
Die Öfen erhalten je einen Einäscherungsraum von nur 600 mm Breite und 450 mm Höhe, da die Verwendung von Särgen nicht geplant ist. Für den Transport der Leichen vom Aufbewahrungsraum bis vor die Öfen empfehlen wir, auf Rädern laufende leichte Transportgestelle zu verwenden und geben wir Ihnen auch für diese eine Massskizze an Hand.
Der für den Betrieb der Öfen benötigte Schornstein muss eine lichte Weite von 500 X 500 mm besitzen und 14-16 m hoch errichtet werden. Lässt sich aus besonderen Gründen ein solcher Schornstein nicht errichten, soviel zwischen Ofen und Schornstein ein Saugzuggebläse zu schalten.
Da die Öfen mit hohen Temperaturen arbeiten, darf die Wandung des Verbrennungsraumes nicht zu schwach sein, um zu vermeiden, dass zuviel Wärme abgestrahlt wird. Die Öfen müssen daher eine äussere

./.

Seit 1863 Didier-Ofenbau!

Document 287: Letter from DIDIER-WERKE AG to Boriwoje Palitsch of 25 August 1943. Document USSR-64.



Breite von ca 3000 mm erhalten. Wir haben aus diesem Grunde den uns vorgelegten Entwurf für dass Gebäude entsprechend ergänzt und überreichen Ihnen anbei ein Skizzenblatt No. 0918 in welchen wir die erforderlichen Mindestmasse eingetragen haben.
Damit Sie in der Lage sind schnellstens ein Vorangebot auszuarbeiten teilen wir Ihnen mit, dass für einen Ofen benötigt werden:

1100 Kg Wölbsteine Segerkegel 33
5500 " Normalsteine " "
1000 " Schamottemörtel
5000 Stück gewöhnliche Ziegelsteine für das Ofenaussenmauerwerk
100 Kg Kalk
3,6 cbm Sand
2,- " Lehm

An Eisenteilen:
500 Kg 8 zur Verankerung
60 " Rundeisenanker
85 " Muffelschiebereinfassung mit Gegengewichten und Seilrollen
40 " Rauchschiebereinfassung mit Gegengewichten und Seilrolle
25 Kg 2 Luftschieber
300 " je eine Feuer, Schlack, und Ascheentnahmetür
25 " Schürstangen
10 " 2 Aschkasten
100 " gusseiserne Roststäbe
80 " Rostauflagerbalken.

Hierzu kommt die gleiche Menge für den 2. Ofen und die Materialien für den Rauchkanal und Schornstein. Auch der Rauchkanal und der untere Teil des Schornsteines ca 3-4 m hoch muss mit Schamottesteinen ausgekleidet werden. Hierfür genügt allerdings eine geringere Sorte.
Die Feuerräume der Öfen wird so eingerichtet, dass neben Koks auch Kohle oder Holz verfeuert werden kann.

Hochachtungsvoll!
Topfofen-Werke A.-G.

Laut Verfügung des Insp. d. Konz. Lager im Einvernehmen des R.S.H.-Amts sollen die Urnen der verstorbenen Häftlinge in einem der hiesigen Gebäude untergebracht werden. Der Kommandant hat deshalb angeordnet, dass hierfür ein Bodenraum im Reviergebäude eingerichtet wird. Damit die Urnen in diesem Raum ordnungsgemäss untergebracht werden können, ist erforderlich, dass entsprechende Regale aufgestellt und kleine Veränderungen vorgenommen werden.
Es wird gebeten, einen Fachmann abzustellen, der die Besichtigung des Raumes vornimmt und die erforderlichen Vorbereitungen trifft.

Preface to the First Edition
Preface to the Second Edition

Unit I: Modern Cremation

1. The Cremation
   1.1. General Principles of Combustion Technology
   1.2. The Chemical Processes during Cremations
   1.3. The Cremation Process
2. Cremation Technology of Coke-Fired Furnaces
   2.1. Structure and Operation
   2.2. General Theoretical and Structural Principles
3. Origin and Development of Modern Cremation Furnaces
4. Cremation Experiments in Germany in the 1920s
5. Technical Developments of Cremation Furnaces in Germany in the 1930s
   5.1. Furnaces with Coke-Fed Gasifiers
   5.2. Furnaces Heated with City Gas
   5.3. Electrically Heated Furnaces
6. The Duration of the Cremation Process
   6.1. Cremation Furnace with a Coke-Fed Gasifier
   6.2. Cremation Furnace with Briquette-Fed Gasifier
   6.3. Cremation Furnace Heated with Gas
   6.4. Cremation Furnace Fired Electrically
7. Heat Balance of a Coke-Fed Cremation Furnace
8. Legal, Ethical and Professional Standards for Cremations in Germany
9. Cremation Statistics
   9.1. Statistics for Germany (1878-1939)
   9.2. Statistics of Other Countries
10. Mass Cremation for Hygienic and Sanitary Purposes
11. Notes on Present-Day Cremation Furnaces

Unit II: J.A. Topf & Söhne

1. Historical Notes on the Topf & Söhne Company
2. The Topf Cremation Furnaces for Civilian Use
   2.1. The Cremation Furnace with a Coke-Fed Gasifier
   2.2. The Gas-Fired Cremation Furnace
   2.3. The Cremation Furnace with Electrical Heating
3. The Topf Patents of the 1920s and 1930s
4. Topf Waste Incinerators
5. Topf Cremation Furnaces for Concentration Camps
   5.1. The Coke-Fired Cremation Furnace with One Muffle

5.2. The Oil-Fired Mobile Cremation Furnace with Two Muffles
5.3. The Coke- or Oil-Fired Cremation Furnace with Two Muffles
5.4. The Coke-Fired Cremation Furnace with Two Muffles Placed Opposite Each Other
6. The Topf Co. and the Construction of the Cremation Furnaces at Auschwitz-Birkenau
6.1. The Furnaces of Crematorium I at Auschwitz
6.2. The Furnaces of Crematoria II and III at Birkenau
6.3. The Furnaces of Crematoria IV and V at Birkenau
7. Structure and Operation of the Topf Cremation Furnaces at Auschwitz-Birkenau
7.1. The Coke-Fired Double-Muffle Furnace Auschwitz Type
7.2. The Coke-Fired Triple-Muffle Furnace
7.3. The Coke-Fired 8-Muffle Furnace
7.4. The Plans for Mass Cremations at Auschwitz-Birkenau
8. The Duration of the Cremation Process in the Topf Furnaces at Auschwitz-Birkenau
8.1. The Documents
8.2. Richard Kessler's Cremation Experiments
8.3. The List of Cremations in the Gusen Crematorium
8.4. The List of Cremations at the Westerbork Crematorium
8.5. Conclusions
9. The Cremation Capacity of the Cremation Furnaces at Auschwitz-Birkenau
9.1. Continuous Operation of the Furnaces
9.2. Concurrent Cremation of Several Corpses
9.3. Soviet and Polish Technical Investigations
9.4. Maximum Theoretical Cremation Capacity
9.5. Normal Cremation Capacity
9.6. Discussion of the *Zentralbauleitung* Letter of 28 June 1943
9.7. The Durability of Refractory Lining
9.8. The Effective Equivalent Operating Time of the Birkenau Cremation Furnaces
9.9. The Auschwitz-Birkenau Crematoria in the General Operation of the Camp
10. Heat Balance of the Topf Furnaces at Auschwitz-Birkenau
10.1. Remarks on the Method Used
10.2. Technical Data
10.3. Heat Balance of the Double-Muffle Furnace at Gusen
10.4. Heat Balance of the Double-Muffle Furnace at Auschwitz
10.5. Remarks on the Heat Balance
10.6. Heat Balance of the Topf Triple-Muffle Furnace
10.7. Heat Balance of the Topf 8-Muffle Furnace
10.8. Observations on the Coke Consumption of the Triple- and 8-Muffle Furnaces
10.9. A Comparison with the Kori Furnace at the Westerbork Camp and the Kori Slaughterhouse Furnaces
10.10. Some Thermal Aspects of the Triple-Muffle Furnace
10.11. On Claims of Flaming Chimneys
11. The Cremation Furnaces Built by Other German Companies: Kori, Ignis-Hüttenbau and Didier

11.1. Historical Remarks Concerning the H. Kori Co. of Berlin
11.2. The Coke-Fired Kori Cremation Furnaces for the Concentration Camps
11.3. The Oil-Fired Kori Cremation Furnaces for the Concentration Camps
11.4. The Oil-Fired Cremation Furnaces Built by Ignis-Hüttenbau A.G. at the Terezín Crematorium
11.5. The Didier Cremation Furnaces for Concentration Camps
11.6. Comparison of the Designs by Kori, Ignis-Hüttenbau, Didier and Topf
12. The Topf Furnaces and Regulations on Cremations in Greater Germany at the Outset of World War II

Appendices

1. Tables
   1.1. List of Cremations at the Westerbork Crematorium
   1.2. List of Cremations at the Terezín Crematorium
   1.3. Summary of the Topf Company's Activities at Auschwitz-Birkenau
   1.4. Patents (and Patent Applications) by J.A. Topf & Söhne
   1.5. Patent Applications by Department "DE" of J.A. Topf & Söhne
2. Glossary
3. Symbols
4. Abbreviations of Archive Names
5. Bibliography
   5.1. Alphabetical Listing
   5.2. Subject Listing
6. Indices
   6.1. Names
   6.2. Concentration Camps
   6.3. Crematorium Locations (Civilian)

Part 2: Documents (separate book)

List of Documents
I. Civilian Cremation Furnaces
II. Topf, Civilian Activities
III. Topf, Correspondence with the SS

Part 3: Photographs (this book)

XIII. Color Documents from Part 2 233

List of Photographs

page
Photograph 1: Original furnace body made of coated sheet metal with added masonry gasifiers at both sides. 25
Photograph 2: Cremation muffles. 26
Photograph 3: Ash doors of the muffles. At the sides the original combustion-air-intake holes. 26
Photograph 4: The furnace's left-hand gasifier with coke-loading door and the gasifier's primary air-intake door (with the shutter missing). 27
Photograph 5: Left-hand gasifier: Inside view, with the first opening connecting it to the left-hand muffle. The refractory brickwork shows evidence of fusion. (For two similar images, see Photographs 315f., which were placed later out of order.) 27
Photograph 6: Left-hand gasifier's primary air intake. 28
Photograph 7: Left-hand gasifier: slag/ash-removal door and service pit. 28
Photograph 8: The furnace's right-hand gasifier with coke-loading door and the gasifier's primary air intake. 29
Photograph 9: Right-hand gasifier: coke-loading door. 29
Photograph 10: Right-hand gasifier: primary air-intake door, ash-removal door and service pit. 30
Photograph 11: Left-hand muffle door: outside. 30
Photograph 12: Left-hand muffle door: inside. 31
Photograph 13: Right-hand muffle door: outside. 31
Photograph 14: Right-hand muffle door: inside. 32
Photograph 15: Left-hand muffle. 32
Photograph 16: Left-hand muffle: ash compartment with two openings connecting it to the gasifier. 33
Photograph 17: Left-hand muffle: inside. 33
Photograph 18: Left-hand muffle: ash compartment. Visible at the bottom left is the first opening connecting it to the gasifier. 34
Photograph 19: Left-hand muffle: Vaulted muffle ceiling with the outlet of one of the pipes connected to a blower. 34
Photograph 20: Left-hand muffle: partition wall with inter-muffle openings. 35
Photograph 21: Right-hand muffle. 35
Photograph 22: Right-hand muffle: to the left the partition wall with three inter-muffle openings. 36
Photograph 23: Right-hand muffle: detail of the partition wall with inter-muffle openings. 36
Photograph 24: Right-hand muffle: inside. 37
Photograph 25: Right-hand muffle: rear wall with opening for the flue gas. 37

page
Photograph 26: Right-hand muffle: Vaulted muffle ceiling with the outlet of one of the pipes connected to a blower. 38
Photograph 27: Right-hand muffle: ash compartment with an opening connecting it to the gasifier. 38
Photograph 28: Right-hand muffle: lateral wall of muffle and ash compartment with an opening connecting it to the gasifier. 39
Photograph 29: Left-hand gasifier. 39
Photograph 30: Right-hand gasifier. 40
Photograph 31: The rear of the furnace with chimney (right-hand side). 40
Photograph 32: The rear of the furnace with chimney going through the ceiling (right-hand side). 41
Photograph 33: The rear of the furnace with chimney (left-hand side). 41
Photograph 34: The rear of the furnace with chimney (left-hand side) with an access door to a pilot flame at the chimney's base. The circular sheet metal welded to the chimney's base closes the original opening for a forced-draft blower. 42
Photograph 35: Upper side of the furnace (from the right). 42
Photograph 36 (top) and 36a (bottom): Original furnace body of coated sheet metal with masonry gasifiers added to its sides. 43
Photograph 37: Original furnace body with left-hand masonry gasifier. The furnace body (with muffle doors, ash doors and original combustion-air-intake holes bolted shut by two discs) is the same as that at the Gusen Concentration Camp. The gasifier sports the large coke-loading door and the small doors for the primary air to the hearth (bottom) and the primary air to the gasifier (top). The ash door is located in the service pit closed by the grate visible at the foot of the gasifier 44
Photograph 38: Original furnace body with right-hand masonry gasifier. 44
Photograph 39: Left-hand gasifier: large coke-loading door (right), small doors for the primary air to the hearth (bottom) and the primary air to the gasifier (top). 45
Photograph 40: Inside of the right-hand muffle with muffle grate. 45
Photograph 41: Vaulted ceiling of the left-hand muffle; to the right: outlets of pipes connected to the blower. 46
Photograph 42: Vaulted ceiling of the right-hand muffle; to the left: outlets of pipes connected to the blower. 46
Photograph 43: Muffle doors. 47
Photograph 44: Outside of left-hand muffle door. 47
Photograph 45: Rear of the furnace, right-hand side. At the top of the gasifier, the rear part of the original oil tank sticks out, which was recklessly walled-in. The furnace's original body is mounted on metal wheels. 48
Photograph 46: Rear side of the furnace seen from the right: Fuel tank (top left) and metal wheels of the furnace body (bottom). 48
Photograph 47: Rear view of the furnace; base of the chimney with an open service door at the right-hand side. The square metal sheet welded to the

page
chimney's bottom closes the opening for the original forced-draft blower..... 49
Photograph 48: Central part of the chimney. 49
Photograph 49: Top part of the chimney. 50
Photograph 50: Left-hand side of the furnace; background: open service door for the pilot flame at the chimney's base. 50
Photograph 51. Furnace front. 51
Photograph 52 & 53: Left-hand muffle. On the left muffle wall four holes for introducing combustion air can be seen. The grate bars are visible beneath the corpse-introduction stretcher. 52
Photograph 54: Left-hand muffle with four holes for introducing combustion air. 53
Photograph 55: Right-hand muffle. On the right muffle wall four holes for introducing combustion air can be seen. 53
Photograph 56: as above. 54
Photograph 57: Combustion-air channel of the left-hand muffle, closed with the door visible in the next photograph. 54
Photograph 58: Door for the combustion-air channel of the left-hand muffle. 55
Photograph 59: Door for the combustion-air channel of the right-hand muffle..... 55
Photograph 60: Vaulted ceiling of the left-hand muffle; outlets of pipes connected to the blower. 56
Photograph 61: Vaulted ceiling of the right-hand muffle; outlets of pipes connected to the blower. 56
Photograph 62: Right-hand muffle; the three inter-muffle openings can be seen to the left. 57
Photograph 63: Left-hand muffle; the three inter-muffle openings can be seen to the right. 57
Photograph 64: as above, close-up. 58
Photograph 65: as above, close-up. 58
Photograph 66: The muffle doors 59
Photograph 67: Left-hand muffle door, inside, and stretcher. 59
Photograph 68: Left-hand muffle door, outside. 60
Photograph 69: Left-hand muffle with open ash door. 60
Photograph 70: Right-hand muffle with open ash door. 61
Photograph 71: Ash chamber of the right-hand muffle. 61
Photograph 72: Ash chamber of the left-hand muffle; at the top the bars of the muffle grate. On the left in the rear part of the wall are two small square openings of a combustion-air intake connected to a channel which opens on the left side of the furnace (see Photos 73f.). In front of those openings is the large opening of the flue-gas outlet; to the right the large opening connects to the ash receptacle of the right-hand muffle. 62
Photograph 73: Left side of the furnace: Door of the combustion-air-intake channel whose channel leads into the ash chamber of the left-hand muffle. 62
Photograph 74: as above, close-up. 63

page
Photograph 75: Rear side of the furnace with the gasifiers. 63
Photograph 76: Air pipe originally connected to a blower. 64
Photograph 77: Rear side of the furnace with the gasifiers and service pit. 64
Photograph 78: Rear side of the furnace with the gasifiers sporting the coke-loading doors (top) the ash-chamber doors (large door at center bottom) and the combustion-air-intake doors (bottom, small doors). 65
Photograph 79: as above; coke-loading door of the gasifier heating the right-hand muffle. 65
Photograph 80: as above, the gasifiers' ash-chamber doors. 66
Photograph 81: as above; the left-hand combustion-air-intake door. 66
Photograph 82: Grate of the left-hand gasifier (viewed from the rear). 67
Photograph 83: Loading system of the right-hand muffle: rod mounted to the frame, movable roller device, and stretcher for the corpse. 67
Photograph 84: as above, left-hand muffle. 68
Photograph 85: as above, viewed from top: the movable roller device on which the bars of the corpse stretcher rests. 68
Photograph 86: Crematorium I or Old Crematorium at the Auschwitz Main Camp. The chimney is a post-war reconstruction. 69
Photograph 87: Furnace no. 1 with two corpse-introduction carts. 69
Photograph 88: as above. 70
Photograph 89: as above. 70
Photograph 90: Furnace no. 2. The reconstruction omitted the transverse anchor bars and the combustion-air-intake channels next to the muffle doors; in addition, the muffle doors were reversed. Compare Photo 51. 71
Photograph 91: as above. 71
Photograph 92: Furnace no. 1: inside of a muffle. The masonry was artificially blackened. 72
Photograph 93: Furnace no. 2: grate of the left-hand muffle. 72
Photograph 94: Furnace no. 2: inside the right-hand muffle. 73
Photograph 95: as above; grate of the right-hand muffle. 73
Photograph 96: Furnace no. 1, right-hand side. Original doors of combustion-air channels. The Polish reconstructions did not include those channels. The number, type and position of the doors are also wrong. The larger door originally belonged to an eight-muffle furnace, and the smaller door was located lower. Cf. Photo 73. 74
Photograph 97: Furnace no. 1, rear side. The furnaces were reconstructed without gasifiers. The gasifiers' coke-loading doors are therefore necessarily in the wrong position over those of the ash-chamber doors. See Photo 78. 75
Photograph 98: Furnace 2, rear: same reconstruction errors as for Furnace no. 1. 75
Photograph 99: Furnace 2: original gasifier grate with seven longitudinal bars and two transverse bars. 76
Photograph 100: Ruins of the foundations of Furnace no. 3: service pit and the

page
gasifier hearths seen from the top. 76
Photograph 101: as above, seen from the rear: original grate of the left-hand gasifier and the two transverse support bars of the right-hand grate. The bar with the rollers, originally attached to the ceiling, was used to operate the furnace's two flue dampers. 77
Photograph 102: Ruins of furnace no. 3: flue-duct opening of the left-hand muffle. 77
Photograph 103: Ceiling of the furnace hall: ventilation opening over Furnace no. 1. 78
Photograph 104: Roof of Crematorium I: The two ventilation chimneys of the cremation furnaces (black and grey). 78
Photograph 105: Transverse rails and rotating platform (turntable). 79
Photograph 106: Turntable for corpse cart. 79
Photograph 107: Crematorium I at Auschwitz: cremation-furnace parts stored in the former coke-storage room. 80
Photograph 108: as above. 80
Photograph 109: as above. 81
Photograph 110: Commemorative plaque in the furnace hall of Crematorium I. 81
Photograph 111: SS photo of the TOPF coke-fired triple-muffle furnaces at Crematorium II at Birkenau. APMO, microfilm no. 287. 82
Photograph 112: TOPF triple-muffle cremation furnaces in the Crematorium at Buchenwald Concentration Camp. 82
Photograph 113: SS photo of the TOPF coke-fired triple-muffle furnaces at Crematorium II at Birkenau. APMO, microfilm no. 290. 83
Photograph 114: TOPF triple-muffle cremation furnaces in the Crematorium at Buchenwald Concentration Camp. 83
Photograph 115: SS photo of the TOPF coke-fired triple-muffle furnaces at Crematorium II at Birkenau. APMO, microfilm no. 290. 84
Photograph 116: TOPF triple-muffle cremation furnace in the Crematorium at Buchenwald Concentration Camp. 84
Photograph 117: as above, coke- or naphtha-fired furnace, front view. 85
Photograph 118: as above, left-hand front view. 85
Photograph 119: as above 86
Photograph 120: as above, right-hand front view. 86

Photograph 83: Loading system of the right-hand muffle: rod mounted to the frame, movable roller device, and stretcher for the corpse.

Photograph 84: as above, left-hand muffle.

Photograph 85: as above, viewed from top: the movable roller device on which the bars of the corpse stretcher rests.

IV. Photographs 86-110: Auschwitz Main Camp

TOPF coke-fired double-muffle cremation furnaces at Crematorium I at Auschwitz Main Camp (postwar reconstruction). July 1992. © Carlo Mattogno for all photographs.

Photograph 86: Crematorium I or Old Crematorium at Auschwitz Main Camp. The chimney is a post-war refabrication.

Photograph 87: Furnace No. 1 with two corpse-introduction carts.

Photograph 88: as above.

Photograph 89: as above.

Photograph 90: Furnace No. 2. The refabrication omitted the transverse anchor bars and the combustion-air-intake channels next to the muffle doors; in addition, the muffle doors were reversed. Compare Photo 51.

Photograph 91: as above.

Photograph 92: Furnace No. 1: inside of a muffle. The masonry was artificially blackened.

Photograph 93: Furnace No. 2: grate of the left-hand muffle.

Photograph 94: Furnace No. 2: inside the right-hand muffle.

Photograph 95: as above; grate of the right-hand muffle.

Photograph 96: Furnace No. 1, right-hand side. Original doors of combustion-air channels. The Polish refabrications did not include those channels. The number, type and position of the doors are also wrong. The larger door originally belonged to an eight-muffle furnace, and the smaller door was located lower. Cf. Photo 73.

Photograph 97: Furnace No. 1, rear side. The furnaces were refabricated without gasifiers. The gasifiers' coke-loading doors are therefore necessarily in the wrong position over those of the ash-chamber doors. See Photo 78.

Photograph 98: Furnace No. 2, rear: same refabrication errors as for Furnace no. 1.

Photograph 99: Furnace No. 2: original gasifier grate with seven longitudinal bars and two transverse bars.

Photograph 100: Ruins of the foundations of Furnace No. 3: service pit and the gasifier hearths seen from the top.

Photograph 101: as above, seen from the rear: original grate of the left-hand gasifier and the two transverse support bars of the right-hand grate. The bar with the rollers, originally attached to the ceiling, was used to operate the furnace's two flue dampers.

Photograph 102: Ruins of Furnace No. 3: flue-duct opening of the left-hand muffle.

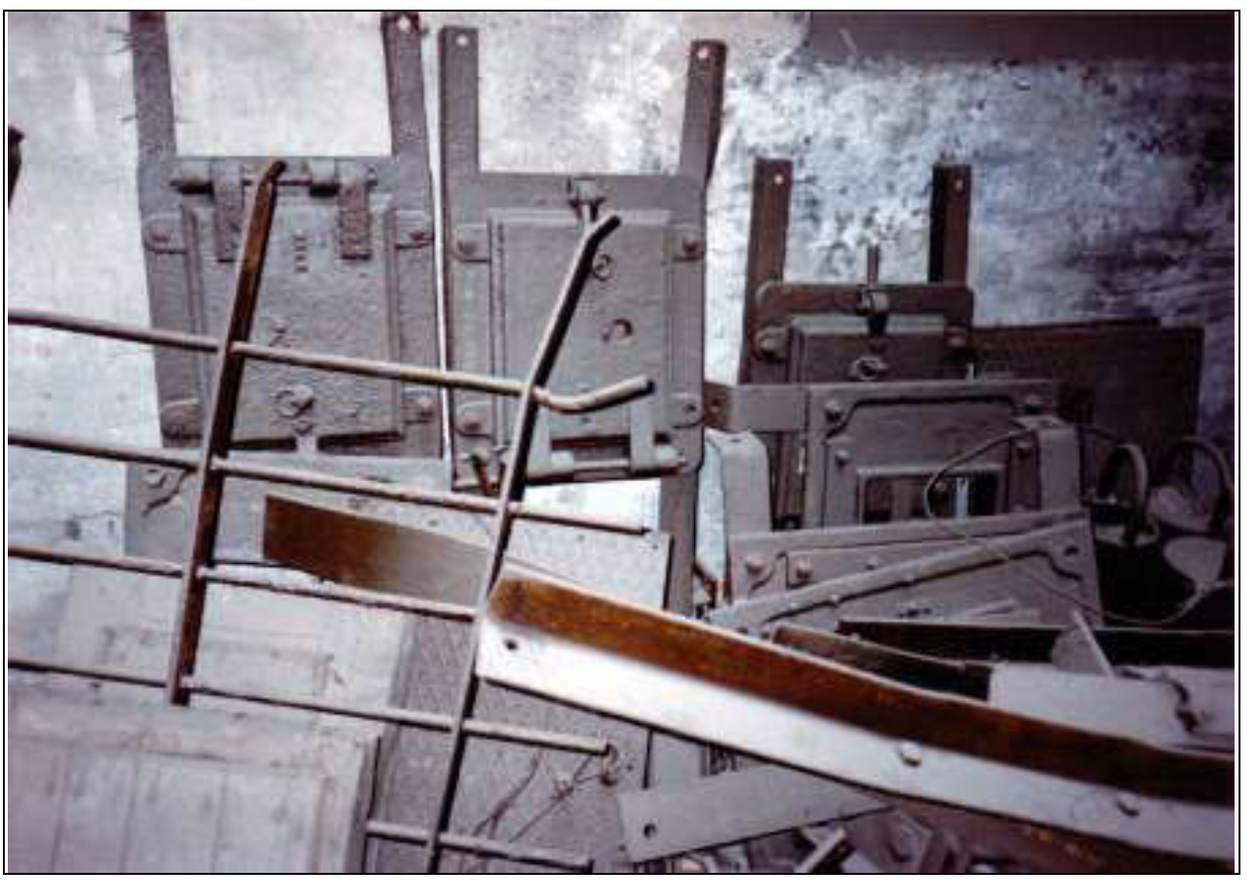
Photograph 103: Ceiling of the furnace hall: ventilation opening over Furnace No. 1.

Photograph 104: Roof of Crematorium I: The two ventilation chimneys of the cremation furnaces (black and grey).

Photograph 105: Transverse rails and rotating platform (turntable).

Photograph 106: Turntable for corpse cart.

Photograph 107: Crematorium I at Auschwitz: cremation-furnace parts stored in the former coke-storage room.



Photograph 108: as above.

Photograph 109: as above.

Photograph 110: Commemorative plaque in the furnace hall of Crematorium I.

Editor's Foreword

The title and subtitle of this book are a provocation. The Auschwitz Museum is one of the most-renowned *and* most-frequented museums in the world, with well over 2.3 million visitors in 2019 according to Wikipedia. How dare we revisionists say that they lie to millions of visitors and deceive them with their exhibits?

The answer to this question is very simple, because the museum officials themselves have already admitted that they lied to every single visitor in the past, because they had been forced to do so by the Polish authorities. This memorable event occurred in 1998, when then-Curator of Research of the Auschwitz Museum Wáclaw Dlugoborski explained to Germany's most-renowned daily newspaper *Frankfurter Allgemeine Zeitung* (*FAZ*) what methods were used before the collapse of the Soviet Union to uphold the lie that four million inmates had died in the Auschwitz Camp during the war – instead of the roughly one million currently claimed:

> *"Up until 1989 in eastern Europe, a prohibition against casting doubt upon the figure of 4 million killed was in force; at the memorial site of Auschwitz, employees who doubted the correctness of the estimate were threatened with disciplinary proceedings."* (*FAZ*, Sept. 14, 1998)

But that situation hasn't actually changed, because today it is illegal in Poland, under threat of imprisonment of up to three years, to dispute any significant detail of the camp's narrative currently told by the Auschwitz Museum. Many other countries in Europe have enacted similar laws. Hence, the Auschwitz Museum officials – and any other scholar involved in this topic – face a very simple alternative: Lie and retain the chance of a comfortable, prestigious career, or forsake all that and go to prison as well. It's that simple.

Which choice will they make? Which choice would you make?

However, it actually doesn't even require criminal laws to keep people from challenging the officially ordained narrative. Anyone stepping out of line even in countries without such legislation will quickly see their reputation tainted, their career destroyed, their social network shredded. This is so because the "Holocaust" is a third-rail topic where dissent is not tolerated by any society.

The question therefore is not whether museum officials at Auschwitz and elsewhere are lying, but whether we can expect them to tell any kind of unwelcome truth, and consequentially become a sacrificial lamb on the altar of the Holocaust religion.

We kick off the present study in Part One with a review of a lie that survived the collapse of the Eastern Bloc for more than a decade: the claim that

the Auschwitz Museum's most-prized exhibit – the camp's crematorium with its claimed homicidal gas chamber – is in its original state as it was used by the evil Nazis for mass murder during the war. That claim was repeated by the Museum's tour guides until around the turn of the millennium, although it can be shown that the Museum's officials responsible for instructing these guides knew better: that building had been completely restructured in 1947 following not solid evidence but Holocaustic propaganda scripts. Hence, although the Soviet Union was gone by 1991 and could no longer serve as an excuse for these officials to perpetuate their lies, they nevertheless kept spreading them – for some ten more years.

Then they changed the narrative a little, without ever admitting having done anything wrong – and without ever apologizing to their millions of deceived visitors.

Yet the current narrative is just as much a lie. They tweaked it a little to patch up some jarring contradictions in the old narrative which had become too obvious to many, but when we look at the details of what they tell visitors today, it's still a pack of lies.

Hence, Part One of this book addresses issues directly affecting millions – the millions of tourists lied to at Auschwitz every year – and could thus potentially benefit both them and countless additional millions of readers.[1]

Part Two of this study, on the other hand, may be of interest only to a select few scholars specializing in the details of archival research on Auschwitz. However, since the orthodox narrative told to millions of tourists rests on the foundations of that archival material, it indirectly affects the whole story more profoundly than anything else. If the Museum's scholars are shown to lie, then the emperor is shown to be naked.

For that reason, the second, much-longer part of the present study is a thorough analysis of the Auschwitz Museum's latest attempt at pulling the wool over the eyes of specialized historians and aficionados interested in the Auschwitz narrative.

Ever since the end of the war, the museum has been desperate to find documentary evidence for the claim that people were mass murdered at Auschwitz in huge chemical slaughterhouses called "gas chambers." They have been utterly unsuccessful with this. Yet they keep on claiming the contrary, while at the same time ignoring all publications refuting their claims. These museum publications, the most-recent of which Carlo Mattogno will cite copiously in his analysis, have been repeatedly revealed as being littered with mistranslations, distortions, inconsistencies, logical fallacies, contradictions and absurdi-

---

[1] Part One of this edition is a combination of text passages taken from the Introduction to the first, 2016 edition of this study, from a chapter contributed to that edition by Eric Hunt (revised and rewritten), and from a paper by Germar Rudolf first published in early 2020 (Rudolf 2020b). Since Eric Hunt prefers not to be associated with this study anymore, we removed his name, although some text passages and ideas contained in Part One were originally his.

ties. Mattogno's devastating analysis laid out in the present book proves these accusations to the point where one is tempted to say: *Enough! Are these Auschwitz scholars insane?*

Probably not. But the mindboggling deficiencies of the latest publication by the Auschwitz Museum left me wondering: How can this be explained? Can the threat of imprisonment in case they decide to dismantle the orthodox narrative really be that powerful that they all fall in lockstep and parrot the same absurd lies without anyone ever disagreeing? Considering that the scholars at the Auschwitz Museum are the High Priests of the Auschwitz Gospel, if they mustered the courage to stand up and say: "Enough is enough, we can't take it anymore!", who could stop them? After all, telling the truth about Auschwitz is a crime primarily and foremost *because* of the utterly immoral lies perpetrated by the "scholars" at the Auschwitz Museum for more than seven decades and counting. Take those "scholars" out of the equation, and the whole thing should collapse.

Of course, these Auschwitz scholars would not merely risk criminal prosecutions, even if they were acquitted at the end of a certainly excruciating, drawn-out procedure. They'd also lose their jobs. They'd end their careers right there. Neither the mass media nor the politicians in Poland or any other nation deeply invested in the myth – first and foremost Germany, the U.S. and Israel – would forgive such iconoclastic heresy.

And then there is what the Germans call *Raubsicherungspolitik* – securing the spoils of a robbery through politics. After World War II, Poland annexed large swaths of Germany and expelled its roughly eight million ethnic-German inhabitants in what constitutes the largest ethnic cleansing in the history of mankind. There is nothing in international law that can ever turn this crime against humanity into a legal, acceptable act. Except, of course, the Holocaust, a sin for which Germany and the Germans must endure any kind of punishment, no matter what. What Poland did right after the war and has been doing ever since, is a simple act of securing her spoils by focusing on German war crimes, by exaggerating them, even by inventing them. Similarly to Israel, Poland's post-war identity is to a large degree based upon her self-promoted image as Germany's victim. And many Poles feel it is important to keep any potential German demand for territorial restitution at bay by constantly waving the Holocaust in everyone's face.

But Poland's existence does not depend on the orthodox Holocaust narrative. Poland existed before the Second World War, and it will keep existing even after the orthodox Holocaust narrative has been cut down to its actual size as supported by verifiable evidence. In addition, Poland has nothing to fear from Germany today. Germany's population is experiencing a demographic collapse. Germans aren't even able to populate what was left to them after the war, let alone any other territories. Ironically, the same is true of Poland, whose demographic trends run pretty much parallel to Germany's. Both

countries are tied to each other by geography, ethnicity, history, culture, and by their current fate of an impending societal collapse triggered by their populations going extinct, plain and simple.

So why bickering about the Holocaust? Why lie about it?

All the more-so since the orthodox Holocaust narrative is the most-important weapon used against any European identity movement trying to prevent or rather revert the collapse of Europe's 4,000-year-old civilization.[2] By simply calling any European identity movement "Nazis" (say: potential gas-chamber mass murderers), any such movement is doomed to fail, and has been failing for decades.

I therefore dare say that those promoting the orthodox Holocaust narrative are the main perpetrators in wiping out European civilization as we know it. And among them, the scholars at the Auschwitz Museum, the holiest of all temples of Holocaustianity, bear the heaviest responsibility.

If Europe's civilization is to become a matter of the past within this or the next century, you can all point at the scholars at the Auschwitz Museum. They did it! Provided anyone is left who might still be interested in knowing who did it.

Part One:

How the

Auschwitz Museum

Dupes Millions of Visitors

The Auschwitz Crematorium I Gas-Chamber Hoax

Introduction

After the former Polish military barracks south of the Polish city of Oswiecim had been converted into a concentration camp by German authorities following the Polish defeat in September 1939, the old munitions bunker on the grounds of that camp was converted into a crematorium for the incineration of the remains of deceased or executed inmates. In war-time and post-war literature, this building is alternately referred to as either the old crematorium or Crematorium I. Subsequent to an initial test gassing conducted in the camp's gaol in early September of 1941 (see Czech 1990, pp. 84-87; Mattogno 2005b), the morgue of this crematorium is said to have been converted into a homicidal gas chamber (Czech 1990, p. 90).

Tourists entering the Auschwitz Museum's main exhibit, which used to be called the Auschwitz *Stammlager* or Main Camp during the war, pass under the infamous "Arbeit macht frei" sign and usually end their tour on the grand finale – Crematorium I with its alleged homicidal gas chamber and cremation furnaces.

Figure 1: "Reconstructed" Crematorium I at the Auschwitz Main Camp. The SS Hospital is located directly behind it.

For decades, tour guides and historians insisted Crematorium I was in its original state. However, a modern sign acknowledges now that Crematorium I existed in a number of layouts throughout the war, and was again modified after the war. This is very much thanks to revisionist researcher Dr. Robert Faurisson who uncovered the original plans of the structure in the Auschwitz archives and shared them with the world.

Figure 2 shows a sign which was set up next to Crematorium I only in recent years. On it, we can see some of the differences between the building in its state at the time of alleged gassings (on the left), and after numerous post-1942 and post-war modifications (on the right).

The museum sign shown in Figure 3, located right next to the one shown in Figure 2, admits:

Figure 2: Sign acknowledging Crematorium I was modified post-war.

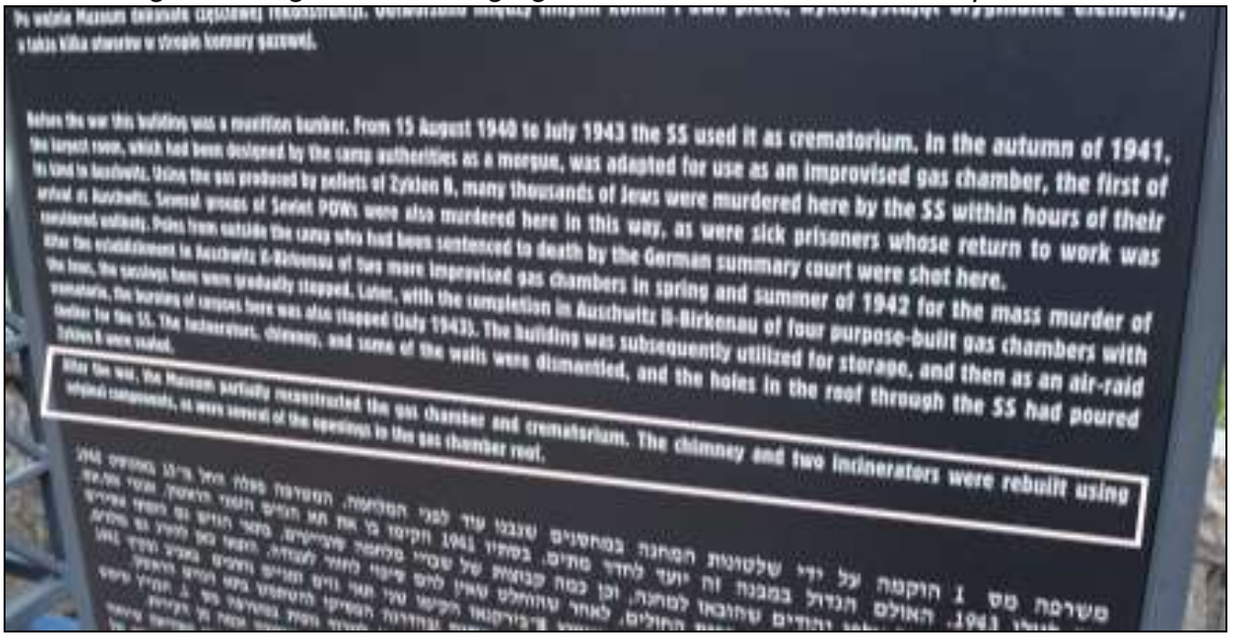

Figure 3: Museum sign explaining a few of the post-war "reconstructions."

> *"After the war, the Museum partially reconstructed the gas chamber and crematorium. The chimney and two incinerators were rebuilt, using original components, as were several of the openings in the gas chamber roof."*

It is therefore indisputable that this building was modified post-war under Soviet occupation and direction to represent a homicidal gas chamber.

Faux Zyklon-B Holes

The only sinister feature of this alleged homicidal gas chamber are four openings in the ceiling, framed by wooden boards and closed by equally wooden lids. For decades, the Auschwitz Museum has claimed through its tour guides that these four openings were used by the evil SS to pour Zyklon B onto inmates trapped in that room in order to asphyxiate them swiftly. Revisionist researchers, such as Robert Faurisson (who called that facility "a 'reconstructed' room" – note his quotation marks; Faurisson 1980) and Ditlieb Felderer (1980), were suspicious early on about the museum's claim that what we see in that building is authentic. However, it took a young Jewish activist to bring this entire problem center stage:

In the summer of 1992, the U.S.-American atheist Jew David Cole went to Auschwitz and recorded on video tape what the attractive young Polish tour guide there was telling him about the alleged gas chamber inside Crematorium I at the Auschwitz Main Camp. She claimed that everything David was seeing there was indeed authentic, genuine and in its original state (Cole 1993, starting at 9:47).

Later during his tour, David managed to interview Franciszek Piper, at that time curator of the museum's historical archives. He confirmed in front of David's camera that what tourists are seeing to this day is neither authentic nor genuine nor original. It was all "reconstructed" shortly after the war to look similar to what the Auschwitz Museum's authorities claimed back then it would have looked when this place was allegedly used by the SS to mass murder Jews and other inmates with poison gas.

In particular the four holes in the ceiling of the purported gas chamber, through which the SS murderers ostensibly poured in the lethal Zyklon-B pellets, were confirmed by Dr. Piper to have been put into place after the war on orders of the museum authorities. Yet Piper insisted that they were put at exactly the same spots where the old, SS-made holes had been, as traces of these holes, which were supposedly filled up by the SS in 1943 or 1944, were allegedly still visible after war's end (Cole 1993, 28:38-28:51).

Fact is, though, that until the turn of the 20th to the 21st Century, Auschwitz Museum officials told their tour guides to tell tourists a claim of authenticity which the officials knew was not true. So they had their tour guides convey a lie to the millions of tourists visiting that most-revered, holy shrine of

Holocaustianity every year. They lied, plain and simple, though the guides may not have known it, or cared.

That changed later, though. After having been deeply embarrassed by David Cole's revealing exposé, the museum officials finally mustered the decency to own up to this deception and put up some signs openly admitting these post-war changes. On another sign, the Museum juxtaposes the building's layout as shown in blueprints of the year 1942 (when the building's morgue was allegedly used as a homicidal gas chamber) with today's layout, although without explaining much of anything. (See the illustrations in Part One of the present book.) It's up to the visitor to make sense of it all.

For the critical investigator, the first pivotal question is: what evidence exists for the Auschwitz Museum's claim that right after the war there were traces of former openings visible on the ceiling of that building's former morgue? Because if there weren't any such traces, then any claims to the contrary would be yet another Auschwitz lie by the museum officials. If there weren't any traces of holes, then the claimed holes never existed in that ceiling. And if those holes never existed, then no SS man ever poured Zyklon B through that roof, as many witnesses have claimed. And in inexorable consequence, this morgue then could not have served as a homicidal gas chamber as claimed by the museum.

This question is therefore at the very center of the entire issue.

Do we have to simply take Dr. Piper's word at face value, who was merely a small child at war's end (he was born in 1941), and thus cannot possibly know from his own experience what he is telling us about the state of the building at war's end? Or do we have to take at face value the statements of any other person who has claimed to have seen these holes during the war?

As Carlo Mattogno has shown elsewhere (2005a, 89-97; 2017, pp. 355-372), these witness statements are highly contradictory not only regarding the number and shape of these holes. They are actually unreliable for many different reasons: internal inconsistencies, conflict with material and documentary evidence, physical and technical impossibilities, obvious absurdities, and clearly propagandistic overtones, to name only a few. Hence relying on those statements does not comport with an investigator's claiming to be critical.

Insofar as reliable documentary or physical evidence is concerned, it is therefore unknown in what exact condition this building was in early 1945 when it was taken over by the Soviets. The late French orthodox historian Jean-Claude Pressac, who has thoroughly investigated the Auschwitz Museum's archives with the full support of the museum authorities, wrote about that (1989, p. 133):

> *"It would appear that the photos of the interior showing the state of the premises were not taken at the beginning of 1945, which is a pity because the restructuring of the building back into a Krematorium began immedi-*

> *ately after the liberation.* […] *Because of the lack of original documents and the transformations that have been made (see the drawing of the present state of the premises at the end of this chapter), it was not possible before to materially demonstrate the existence of a homicidal gas chamber in the former morgue of Krematorium I."*

But we didn't want to take Pressac's word at face value either, so a friend of mine, unsuspected of harboring any iconoclastic views, managed to get a well-established academic involved in research of a similar nature to approach the current director of the Auschwitz-Museum, Dr. Piotr Setkiewicz, with two simple questions asked in a letter dated March 14, 2016:

> *"1) Did Soviet or Polish authorities document, or photograph, the interior of the crematorium, before any alterations were done? I would like to know about the layout of the interior, ceiling openings, and so on. Are there any photographs, drawings, or descriptions? If so, can I obtain copies?*
> *2) It is clear that Soviet/Polish authorities made significant post-war modifications to the building. Is there any documentation about this? Any description or documents showing the work performed—that is, anything about cost estimates, blueprints, work orders, materials, etc? And again, if so, can I obtain copies?"*

Here is what Dr. Igor Bartosik from the Museum's Research Center answered in a letter dated March 31, 2016 (see reproduction on p. 38):

> *"Dear Sir*
> *In response to the letter from 14 March, I would like* [to] *inform* [you] *that unfortunately we can not help you. Our museum does not have any documents on matters that interest you.*
> *From the memories of former employees (very often ex-prisoners) we know that the work on the reconstruction of furnaces, chimney etc.,* [were] *made in the second half of 1947.*
> *Best regards*
> *dr Igor Bartosik"*

So, now we have it from the horse's mouth: There is no evidence at all as to the exact condition this building was in at war's end, and the changes made to turn that building into the museum's most-prized exhibit were not documented either.

Asked which "memories of former employees" contain information about the reconstruction, Dr. Bartosik referred to the testimony of Adam Żłobnicki dated 18 November 1981. Żłobnicki had been interned at Auschwitz during the war with the inmate number 165010, and had worked as a guard at the Auschwitz memorial since 13 June 1946.

If we follow Żłobnicki's statement, he remembered that right after the war Krematorium I had no chimney, and that the interior of the gas chamber

looked different from what it looked like later. On the holes in the ceiling of this room, Źłobnicki stated the following:[3]

> *"I remember exactly that the introduction holes for the Zyklon-B gas, which used to be in the roof of the crematorium, were also reconstructed. The task of those charged with this reconstruction was facilitated by the fact that distinct traces of the cement patches of the earlier openings were left in the spots of the old introduction holes. Hence new openings were broken through at the same spots, and little chimneys* [i.e. introduction shafts] *were built with bricks* [*domurowano*]. *This work was also done in the years 1946-1947."*

The first question that comes to mind, how a guard not involved in the reconstruction could know any details of what was going on inside the building during the reconstruction? This is all the more disturbing as what he says about the newly built introduction shafts is wrong: they were and still are merely lined with wooden boards, not made of bricks.

The next question is: If the museum authorities never had any documentation on the exact state of that building before its "reconstruction", and none about the changes made during that process either, why didn't they approach anyone involved in that reconstruction to have their testimony recorded, such as any former museum official in a position of responsibility back in 1947, or any person involved in the actual work, such as architects, engineers, construction workers, you name them. Why, of all possible people, did they ask a non-involved memorial guard?

Fact is that all we have is an inaccurate account from a bystander, who may or may not have adjusted his account to what those recording it – the Communist museum officials of the early 1980s – wanted to hear from him.

Any assertion by any employee of the Auschwitz Museum that the current holes were opened at exactly the same locations as they had been during the war is therefore based not on solid, reliable evidence at all. They may or – considering what is at stake for them – they actually *must* be convinced that what Źłobnicki stated is true, yet that doesn't make it true.

But what *is* true?

We know that the Polish legal authorities initiated large-scale criminal investigations against the former camp commandant Rudolf Höss and against the entire staff of the Auschwitz camp garrison right after the camp's occupation by the Soviets. To this end, they collected all kinds of evidence in support of mass-murder claims. Photos of the claimed mass-murder sites as found right after the Soviet occupation would have been of the utmost importance, in particular if they could support any mass-murder claims.

The fact that no such photos of the ceiling of the alleged former gas chamber in Crematorium I exist raises the suspicion that such photos would not

---

[3] APMO-B, Statements, vol. 96, p. 60.

have shown what the Soviet and Polish authorities wanted the world to believe. This suspicion is supported by the fact that no document exists regarding the changes made to this entire building in 1947. This indicates that the motivation behind those changes was *not* to meticulously restore something as accurately as possible, but to cover up manipulations.

Today we can infer these postwar changes only by comparing the current state with German construction blueprints of the wartime.

The undocumented manipulation of evidence that is central to a criminal investigation is itself a crime, by the way. Wikipedia writes in its entry on "Spoliation of evidence":

> *"The spoliation of evidence is the intentional, reckless, or negligent withholding, hiding, altering, fabricating, or destroying of evidence relevant to a legal proceeding. Spoliation has three possible consequences: in jurisdictions where it is the (intentional) act is criminal by statute, it may result in fines and incarceration* […].
> *The spoliation inference is a negative evidentiary inference that a finder of fact can draw from a party's destruction of a document or thing that is relevant to an ongoing or reasonably foreseeable civil or criminal proceeding: the finder of fact can review all evidence uncovered in as strong a light as possible against the spoliator and in favor of the opposing party."*

In most countries, Poland included, tampering with evidence is illegal und can thus be prosecuted. We are therefore not dealing merely with a case of sloppiness here, but with a potential crime of the Soviet and/or Polish officials involved in "reconstructing" Crematorium I right after the war, whoever they were.

The Orthodox Position

As explained by Piper, the Auschwitz Museum's position is that these holes were "re-made" in the exact locations of the pre-existing, genuine holes, which were allegedly used in 1942 and 1943 to drop Zyklon B on the heads of those inside. In the fall of 1944, when the Germans converted the section of the old crematorium that contained the morgue/"gas chamber," the washroom and the laying-out/dissecting room into an air-raid shelter for the nearby SS hospital,[4] they allegedly filled in these holes with some concrete.

The Revisionist Position

However, the four holes in the roof of the morgue of Crematorium I at the Auschwitz Main Camp do not "fit" the original configuration of the building. In fact, they are centered over the *current* post-war-modified configuration of

[4] This conversion results from a letter dated August 26, 1944, by Heinrich Josten, head of the Auschwitz air-raid protection department, to the camp commandant, RGVA 502-1-401, p. 34.

the expanded room. The first to point this out was Germar Rudolf in the first, 1993 German edition of his expert-witness report on the chemistry of Auschwitz (in Chapter 1.2.). In the current English edition of 2020, this slightly expanded passage can be found in Chapter 5.3. (Rudolf 2020a, pp. 101f.):

> *"If the SS had put these holes in the concrete during the war, one must assume that they would have taken care to evenly distribute these holes in the ceiling of the original(!) morgue in order to ensure an even distribution of the Zyklon B inside the room. The shafts today, however, are only evenly distributed in the ceiling of this room if one considers the washing room, which was only incorporated after the war(!), as an integral part of the morgue ('gas chamber'.)* […].
>
> *Thus, the arrangement of today's introduction holes only makes sense if they were created especially for its present status as a falsely dimensioned 'reconstruction for Museum purposes'* after *the war. This becomes even more evident from Figure 55, which shows the same section of Crematorium I as in Figure 54 as a 3D model, yet in the current state. This shows that the holes' locations were chosen with precision in order that crossing pairs are equidistant to the nearest transverse wall, leading to all four holes being somewhat evenly distributed over this room. This is the decisive evidence that these holes were created with regard to the measurements of the accidentally enlarged morgue/'gas chamber,' and have nothing to do with the original morgue."*

Carlo Mattogno expanded on that theme in three studies by investigating this issue more deeply (2004c; 2005a, 89-97; 2017, pp. 355-372).

The 3-D model of Figure 55 mentioned by Rudolf in the above quote – not contained in the original 1993 edition of his work – was actually taken from the first, 2016 edition of the present book. A 3-D representation of the relevant section of Crematorium I is indeed useful to understand this "hole hoax."

For these basic 3-D representation, the "roof" of the building (dark grey) has been lowered so the interior walls can be seen. The rear half of the building is devoted to the furnace room and additional smaller rooms, and has not been represented in this 3-D rendering.

Figure 4 shows Crematorium I at the time of alleged mass gassings. The four claimed, square-shaped Zyklon-B-insertion holes are represented in the roof. The large rectangular room designated as a morgue on the original German plans is the alleged gas chamber. This of course raises the question: what part of this building was used as a morgue instead, if the actual morgue was used as a gas chamber?

As we can see, the placement of the holes seems wrong, and they are not centered over the long rectangular morgue, the alleged gas chamber. Wouldn't any sensible engineer and construction worker place these holes in such a way that they are somewhat evenly distributed over the entire ceiling in order to

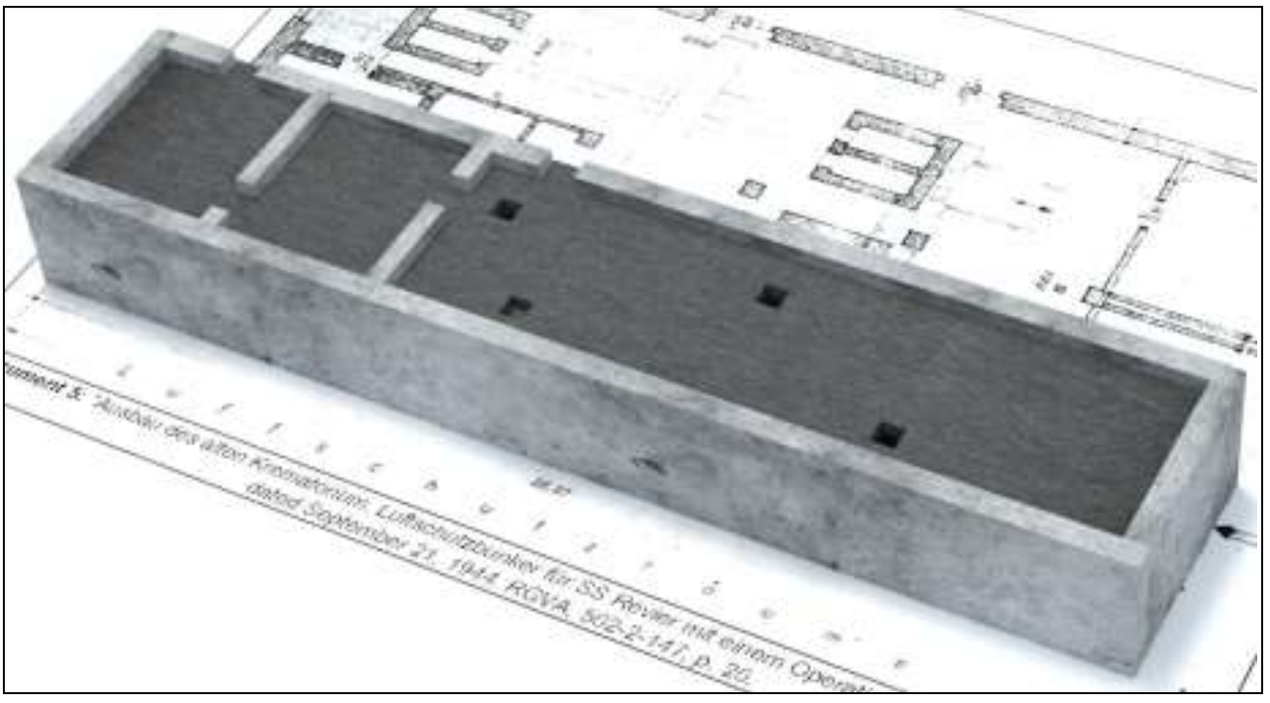

Figure 4: Configuration at time of alleged mass gassings (but see fn 11 on p. 37).

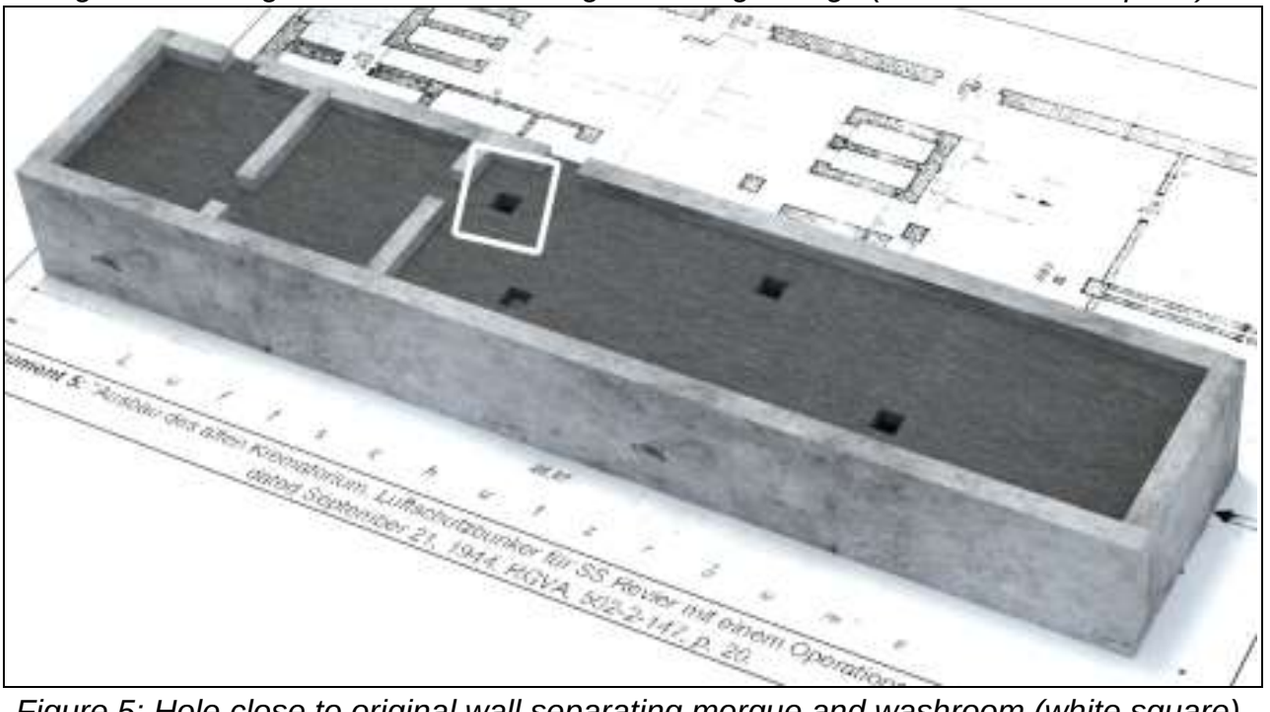

Figure 5: Hole close to original wall separating morgue and washroom (white square).

make sure that the poisonous fumes get evenly distribute throughout the entire "gas chamber"?

Figure 5 shows the location of an oddly placed hole, highlighted by a white square, which is very close to the location of both an original wall separating the morgue from the washroom next to it, and the door to the furnace room. This hole is shown in Figure 6. The beam coming from the left was once a wall. This wall was removed during the 1947 "reconstruction."

After the larger purpose-built crematoria at the nearby Birkenau Camp started operating in early 1943, Crematorium I was first retired, then, in late 1944, converted into an air-raid shelter for the SS hospital located across from

Figure 6: Photograph of hole near original dividing wall and door.

it. In Figure 7, we can see the many interior walls added, as well as an additional entrance/exit and air lock on the right. The doorway between the morgue/alleged gas chamber and the furnace room was walled up.

The current configuration, shown in Figures 8 and 9, is highly revealing. The museum knocked down one wall too many – the one originally separating the morgue from the washroom during the time of alleged gassings. They also created a new opening allowing tourists to walk from the morgue/"gas chamber" directly into the furnace room, although they created that opening at the wrong location (and with a larger and asymmetrical size; plus they didn't install any door at all into this opening…).

Note that now, all of a sudden, those four Zyklon holes appear to "fit," meaning they are somewhat evenly distributed across the ceiling of the current, accidentally(?) enlarged "gas chamber" tourists walk into.

According to Carlo Mattogno's measurements, the holes in the upper left and lower right are 5.1 meters away from the current walls. But during the war, when the room is said to have been use as a gas chamber, the hole in the upper left was barely a meter away from the now-removed dividing wall to the washroom.

The other two holes are 7.1 meters away from currently existing walls. One of the walls, however – the one on the right separating the morgue from the air lock – didn't exist at the time of alleged gassings, because it was added only in 1944 during the building's conversion to an air-raid shelter! The actual distance in 1942/43 would therefore have been some 9 meters, not 7.1 meters. In 1942/43, the distance between the other hole and the closest wall to the left – the now-removed washroom wall – would have been some 3 meters only.

The placement of the holes in the roof of Auschwitz's Crematorium I are centered over a building configuration which only existed after the post-war modifications.

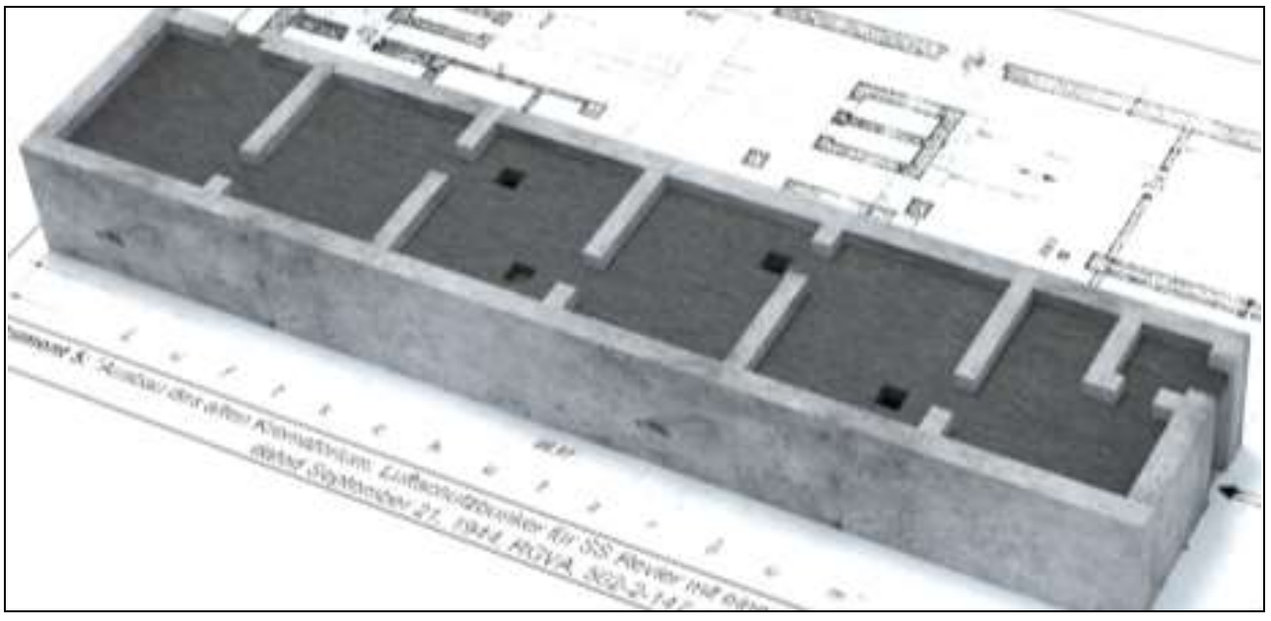

Figure 7: Air-raid shelter configuration of late 1944/early 1945.

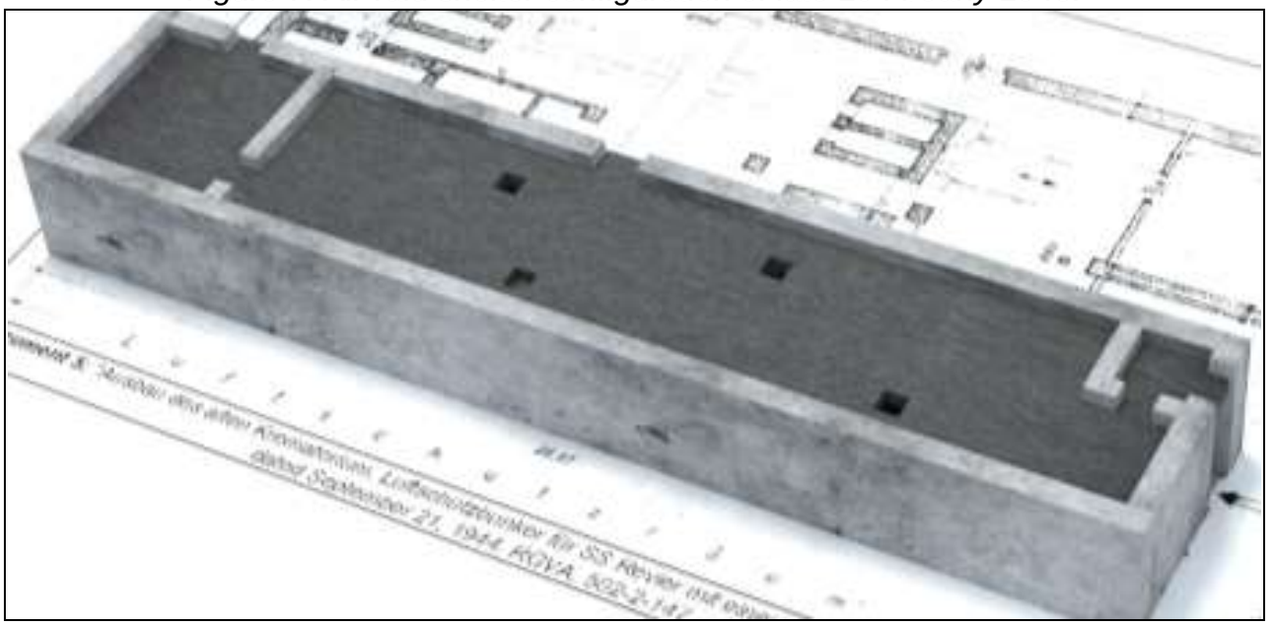

Figure 8: Current Configuration as "reconstructed" in 1947 by the Auschwitz Museum.

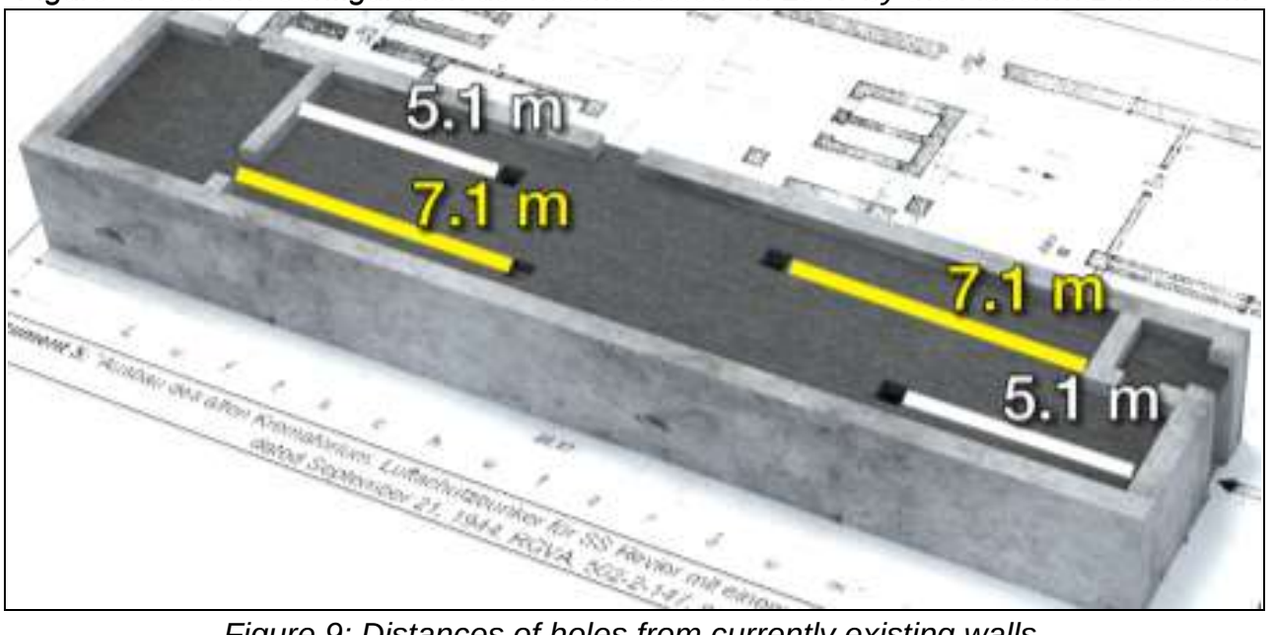

Figure 9: Distances of holes from currently existing walls.

In early 1945, the Soviets found in that building an air-raid shelter for the SS Hospital equipped with an operating room and a set of toilet stalls. This served no use for propaganda. Hence, when "reconstruction" began in 1947, the Polish authorities added a chimney on about the same spot where it was located previously. They rebuilt two of the three furnaces in the furnaces room, albeit in a rather flawed way. Furthermore, they removed all but one of the interior walls dividing up the air-raid shelter, making a big mistake by removing one too many – the original separation wall between the morgue and washroom which existed at the time of alleged gassings. The air-raid shelter's toilet stalls were also removed.

If there had been traces of holes in that ceiling in 1945 that the SS had closed up, then they should never have been "re-opened" in the first place. This would have been tampering with a crime scene of alleged mass murder! And if there weren't any such traces, the whole thing is nothing short of a giant, criminal hoax!

The placement of the currently existing four holes, however, points to a crude mistake on the part of the hoaxers, who centered the supposedly "re-opened" holes not over the morgue as it was in 1942/43, but over the morgue + washroom + 1944 air-lock entrance, *a configuration which did not exist at the time of the alleged mass gassings*.

Majdanek: An Admitted "Hole Hoax" Precedent

Although the scope of this book is focused on the Auschwitz Museum's lies, tricks and obfuscations, Auschwitz is only one part of the larger Holocaust myth. Most people hear for the first time about revisionist claims regarding Auschwitz through the mass media which, with their deceitful rhetoric, make the common reader believe that revisionist claims have no basis in reality and are merely outrageous, absurd and utterly untenable.

However, there is a precedent where a "hole hoax" is today generally admitted to have been committed by the Soviets at war's end. It concerns the Majdanek Camp, and more specifically, a room in this camp's "new" crematorium which served as a morgue during the war. For decades after the war's end, this morgue was alleged to have served as a homicidal gas chamber. To that effect, Zyklon B was allegedly thrown through an opening in the ceiling (see Figures 10-12).

In 2005, however, in a sweeping revision, the director of the Majdanek Museum, Tomasz Kranz, drastically revised the Soviet-derived propaganda death toll down to a mere 78,000 – not even 5% of the original number of 1.7 million as claimed at war's end! (See Graf/Mattogno 2016, pp. 9 and 260-281.) In this radical process of shedding propagandistic ballast, Kranz also jettisoned five of the seven originally claimed homicidal gas chambers at Maj-

danek, thus indirectly admitting that at least $^{5}/_{7}$ of the original Majdanek gas-chamber story was a fraudulent propaganda hoax.

For the crematorium's morgue, this revision was quite inevitable, because the room had no means for ventilation, and even had two openings in a wall with no means for closing them (see Figure 11). Ever since, this morgue has no longer been alleged to have served as a homicidal gas chamber. Yet the room's reinforced-concrete ceiling still has the hole which was obviously cut through after the war, probably by Soviet forgers. The Majdanek Museum remains absolutely silent about it, hoping that visitors won't see it or, if they do, won't ask any embarrassing questions.

Figure 10: Morgue in the New Crematorium of the Majdanek camp, prior to museum revisions. A crudely cut hole in the ceiling was for decades alleged to have been used to drop Zyklon B pellets into the room to gas trapped victims – although those pellets would have fallen directly into a floor drain below. This sign, now removed and revised, deceitfully claimed this was a homicidal gas chamber.

Figure 11: Morgue inside the "new crematorium" at the Majdanek Camp with two openings in one of its walls. Top right: the hole in the ceiling (© 1995 Carlo Mattogno.)

These drastic revisions of the death toll and the claimed homicidal gas chambers are thanks primarily to Jürgen Graf's and Carlo Mattogno demolishing of the Majdanek "death-camp" claims in their book *Concentration Camp Majdanek: A Historical and Technical Study*, which Kranz read, remarked on, and must have been influenced by.

Figure 12: Close-up of the Soviet-made hole in the ceiling of the morgue inside the "new crematorium" at the Majdanek Camp. Note that the forgers did not even bother removing the reinforcement bars. (© 1997 Carlo Mattogno.)

Those new to revisionist research need to understand and recognize the lies about the above-mentioned Majdanek morgue with its "hole hoax," and similar lies about various other rooms once claimed to have served as homicidal gas chambers throughout the German camp system. A multitude of rooms have fraudulently been alleged to have served as gas chambers, yet these claims have been silently dropped in later years. These falsely labeled rooms range from morgues (Majdanek), kitchens (Breendonck, Belgium), clothing-drying facilities (Majdanek), fumigation rooms (Majdanek), shower rooms (Majdanek) to clothing steamers (Natzweiler, France). "Holocaust" claims such as these are truly absurd, quite in contrast to revisionist analysis of the physical evidence, documentation and eyewitness errors and falsehoods.

The false claims about the Auschwitz morgue/"gas chambers" belong in the dustbin of history, along with the previously abandoned claims of the Majdanek morgue/"gas chamber."

The "Victims' Entrance"

In their post-war remodeling of Crematorium I, the Polish authorities left the air lock with the second entrance added in 1944 in place. Despite revisionists pointing out the fact that this entrance was created after the time of alleged gassings, the museum authorities passed it off to visitors for the entire rest of the 20th Century as the "victims' entrance."

As recently as 1999, and according to available information even many months if not years afterwards, tourists would first walk past the gallows allegedly used to hang Rudolf Höss. A sign shaped as an arrow pointed to "Crematorium I's" air-raid-shelter door as the "victims' entrance" (see Figure 13). However, neither the gallows nor the air-raid-shelter door existed at the time of mass gassings! Clearly both add to the theatrics. Yet for decades, tourists were told by tour guides that this was the way the victims entered the

Figure 13: A composite of two photographs taken in 1998.

death chamber. The museum tour guides, again improperly instructed by the museum's officials, told a lie, whether they were aware of it or not.

The anti-revisionist film *Mr. Death* directed by Jewish filmmaker Errol Morris used the air-raid-shelter door to great effect. Using tilted, also known as canted or "Dutch" camera angles, along with Halloween horror music, the air-raid-shelter door is shown as proof of sinister Nazi-gas-chamber doors (Figure 14).

As Morris shows the rusty air-raid-shelter door at Auschwitz filmed like a B-grade horror movie, Jewish "Holocaust expert" Robert Jan van Pelt claims revisionists sicken him. Next, a composite shot using fake special effects is a truly shocking low for the Holocaust industry. For that footage, Errol Morris used a different-aged steel door with a peephole, and composited a shot of the inside of the "gas chamber." All this is an attempt to trick viewers into thinking that the steel door at Auschwitz was centered on, and looked right directly into, the "gas chamber." Van Pelt even looks through the Hollywood prop door peephole, mimicking an SS officer watching Jews being gassed (Figure 15a-c).

Figure 14a-c: Screenshots from Mr. Death *(1999), the "victims' entry."*

Figure 15a-c: Fake footage in Errol Morris's film Mr. Death.

However, the actual air-raid-shelter door at Auschwitz is not grey but simply rusty brown, as it consist of a mere wooden door with a piece of sheet metal nailed to it to make it gas-tight. Furthermore, in the 1980s, David McCalden pointed out that this air-raid-shelter door opens right into another wall within arm's reach (Figure 16a-d)! Hence the SS could not have watched Jews getting gassed through that peephole for two reasons: first because one would have looked right into another wall, and second because this door wasn't even installed until after the alleged gassings had ended! Morris and van Pelt are forced to use cheesy Hollywood special effects to con their viewers.

According to surviving German documentation, this gas-tight door was ordered and put in place to protect lives in case of poison-gas attacks from *outside* the building (from aerial bombing)! Every viewer of *Mr. Death* was conned by a total inversion of reality.

In more-recent years, the Auschwitz Museum changed its narrative while being absolutely unapologetic for the fact that they had been lying to visitors for decades. The entranceway fitted with the air-raid-shelter door is now no longer used by tourists to enter the building. In fact, this entrance is physically closed to tourists by a chain and sign saying "No Entrance" (Figure 17). In addition, from layout drawings shown on a sign displayed in front of that crematorium, tourists *can infer* that this entrance did not exist when the place was said to have been used to mass murder people – although it is not expressly stated in the drawings' caption. But how many tourists actually look thoroughly at those drawings and make inferences about construction details?

Nowadays, the Auschwitz Museum instead herds gullible tourists through the entrance on the opposite side of this building. They are now told that the

Figure 16a-d: First three images: stills of the air-raid shelter entrance from the revisionist documentary "The Holocaust Revisited." Last image: section from today's museum sign with an arrow added pointing in the line of gaze of Figure 16b (rusty air-raid shelter door with peephole, closed) and c (door opened, wall behind it visible).

supposed victims had to walk through two separate rooms in order to enter the "chamber."

It is clear why the Auschwitz Museum for all of last century herded tourists through the air-raid-shelter entrance. The entrance's sloping, claustrophobia-inducing walls and its sturdy steel door with the sinister myth surrounding its peephole were a great choice for traumatizing visitors. The air-raid-shelter entrance also makes more sense than the current tourist path, because had it existed at the time, the supposed victims could have walked almost directly into the "gas chamber."

The current tourist pathway through Crematorium I, which would also have been the victim's parthway during the war, goes through two rooms (labelled a and b on the museum's map), whose wartime function would have made it impossible to hide from inmates that prisoners were dying in masses in that building. One of these rooms (b), a "washroom" according to wartime blueprints, was supposedly "used to store the ashes of incinerated corpses," if we believe the map's caption, while the other is labeled as a "laying-out room" in the blueprints, that is to say: this is where corpses were stored, prepared for and subjected to autopsies. The other theoreti-

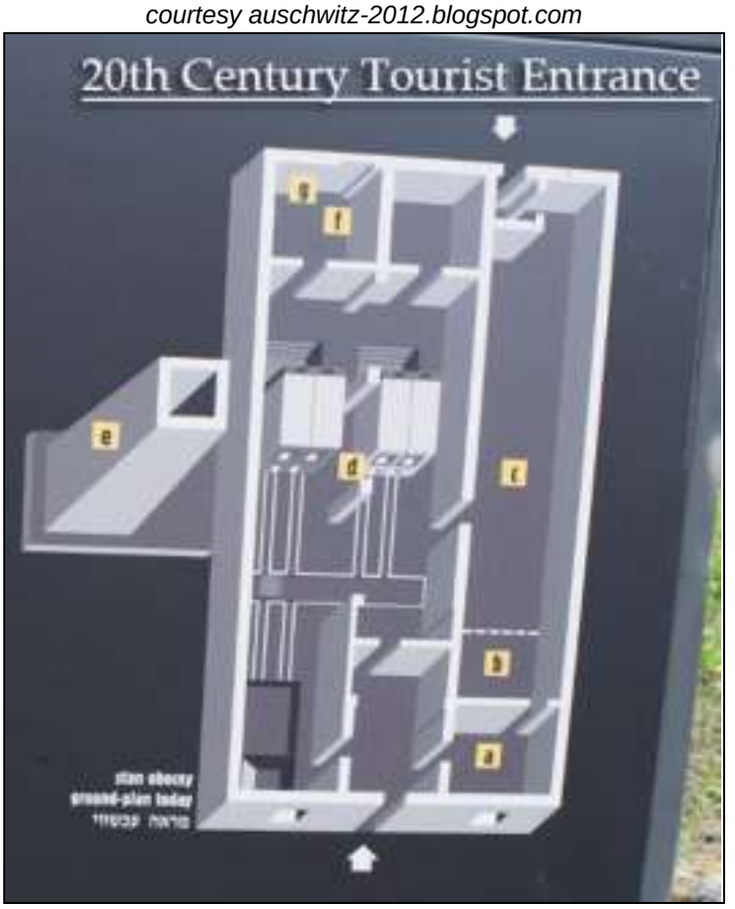

Figure 18: The 20th-century tourist entrance (top) through the air-raid shelter's access door is now closed. Tourists are instead herded into this building through an entrance pointed to by the white arrow at the bottom of this map.

cally possible pathway is even dumber: victims would have been forced to walk right past the cremation furnaces! Either of these victims' pathway choices, "newly revised for the 21st Century," would have made any intended victim aware that they were in a veritable "death building", with corpses and their ashes stacked everywhere for them to see. And yet, they are claimed to have walked calmly into the death chamber, presumably blissfully ignorant of what was coming, just like sheep to the slaughter…

The Doors

The two doors which allowed access to the room within Crematorium I that is said to have been used as a homicidal gas chamber in 1941-1943 are of pivotal importance, because they would have been used to securely trap poisonous fumes and hundreds of potentially panicking victims inside. The questions to ask in this regard are:

1. What kind of doors would have been needed for such a task?
2. What kind of door did the room actually have?

Door Type Needed

Keeping a potentially panicking crowd locked inside a room, and at the same time preventing toxic gases from seeping through the door, requires a tightly sealed, massive steel door that is firmly anchored into a sturdy wall. Such doors were mass-produced in Germany during the war for use in Germany's thousands of air-raid shelters.

Doors Claimed by Witnesses

The orthodox narrative does not rely on material traces or documents, but solely on accounts given by witnesses. One of the first documents based on such eyewitness claims is the report by a combined Polish-Soviet investigative commission, which stated already two months prior to the end of World War Two the following about the doors leading into the claimed gas chamber:[5]

> *"In early 1941, a crematorium, designated as Crematorium #1, was started up in the Auschwitz camp.* […] *Next to this crematorium there was a gas chamber, which had, at either end, gas-tight doors with peep-holes and in the ceiling four openings with hermetic closures through which the 'Ziklon'* [sic] *for the killing of the persons was thrown. Crematorium I operated until March 1943 and existed in that form for two years."*

In preparation for the 1947 Polish show trial against former Auschwitz Camp Commandant Rudolf Höss, Polish engineer Dr. Roman Dawidowski compiled

---

5 GARF 7021-108-15, pp. 2f.

an expert report on evidence supporting homicidal gassing claims at Auschwitz, where we read on this topic:[6]

> *"One now* [in late 1941[7]] *began to poison people regularly with Zyklon B and to use for that purpose the Leichenhalle (morgue) of Crematorium I* […]. *This chamber* […] *on both sides had a gas-tight door."*

Jan Sehn, the Polish judge who led the investigation leading up to the Polish post-war show trials against former members of the German Auschwitz Camp staff, wrote the following about this in his 1960 book on Auschwitz (Sehn 1961, p. 125):

> *"The mortuary (Leichenkeller)*[8] *of the first Oswiecim crematorium* […] *was fitted with two gas-proof doors."*

Claims about gas-tight doors in that morgue originate from witness testimony. Among them is Stanisław Jankowski, who stated regarding the doors in that room in a deposition October 3, 1980 (Pressac 1989, p. 124):

> *"The two thick wooden doors of the room, one in the side wall, the other in the end wall, had been made gas-tight."*

The post-war autobiography of Rudolf Höss, written while in Polish custody awaiting his execution, contains little information about the doors of this alleged gas chamber, only that they must have been very sturdy, because (Bezwińska/Czech 1984, p. 93):

> *"When the powder* [sic; Zyklon B] *was thrown in*[to the gas chamber], *there were cries of 'Gas!', then a great bellowing, and the trapped prisoners* [Russian PoWs to be gassed] *hurled themselves against both the doors. But the doors held."*

Höss moreover speaks repeatedly of the doors being "screwed" shut (*ibid*., pp. 96, 115, 134), which points to a door with massive steel fixtures not found on usual doors.

In his post-war declaration writing in the summer of 1945, former SS man Pery Broad was a little more specific about the doors of this claimed homicidal gas chamber, making it clear that this was a heavy, gas-tight, panic-proof door (*ibid*., p. 176):

> *"Suddenly the door was closed. It had been made tight with rubber and secured with iron fittings. Those inside heard the heavy bolts being secured. They were screwed to with screws, making the door air-tight. A deadly, paralysing terror spread among the victims. They started to beat upon the door, in helpless rage and despair they hammered with their fists upon it."*

---

6 AGK, NTN, 93. The report entered the files of the Höss Trial in its Volume 11. The quoted passage is on pp. 26f.

7 Danuta Czech set the date of the first gassing in that morgue to September 16, 1941; Czech 1990, p. 90.

8 That should be *Leichenhalle*, as it was above-ground, while "Keller" means basement/cellar.

While interrogated in preparation of the first Frankfurt Auschwitz Trial, defendant Hans Stark made the following statements in his deposition about the doors of that room:[9]

> *"As early as the autumn of 1941 gassings were carried out in a room of the small crematorium, the room having been fitted for that purpose. It could take in some 200–250 people, was higher than a normal living room, had no windows, and only one door that had been made* [gas] *tight and had a lock like the door of an air-raid shelter."*

We conclude from this that heavy, gas-tight, sturdy doors must indeed have been installed in that facility, if we are inclined to believe these witness reports.

Doors According to Material Traces and Documents

The Current Situation

As mentioned before, for several decades after the war, tourists visiting the museum entered the building using an opening that has a wooden door clad in a sheet of iron and equipped with an ominous-looking peephole. Superficially seen, this door looks like the kind of door that could have been used in a homicidal gas chamber, although it was made merely of wooden boards and was therefore hardly panic-proof. The problem is that this door was added to this building only in late 1944 when it was converted to an air-raid shelter. Hence the door we see there today is an absolutely innocuous air-raid-shelter door.

The second door contained in this room on display as a "gas chamber" that leads into the former laying-out room is an even flimsier wooden door which even has a thin, easily breakable window pane. In addition, there is no door at all in the wall opening connecting that morgue/"gas chamber" with the furnace room. It goes without saying that no room thusly equipped could have operated as a gas chamber. However, since it is admitted today that this is not what the place looked like originally, basing an argument on these doors would be rather pointless. Hence I abstain from illustrating these doors and the wall opening to the furnace room. It just emphasizes the fact that what we are shown there today does not merit the term "reconstruction."

The Door between Furnace Room and Morgue

The only original door of that room about which we have any revealing information – gleaned from original wartime blueprints – is the one connecting the morgue a.k.a. "gas chamber" to the furnace room. On all extant blueprints showing doors, this opening is shown as having had a swing door (see Figure 19 with a plan of 1940, and Figure 20 with a plan of 1942).

---

[9] Minutes of interrogation of Hans Stark, Cologne, April 23, 1959. Zentrale Stelle der Landesjustizverwaltungen, Ludwigsburg, ref. AR-Z 37/58 SB6, p. 947.

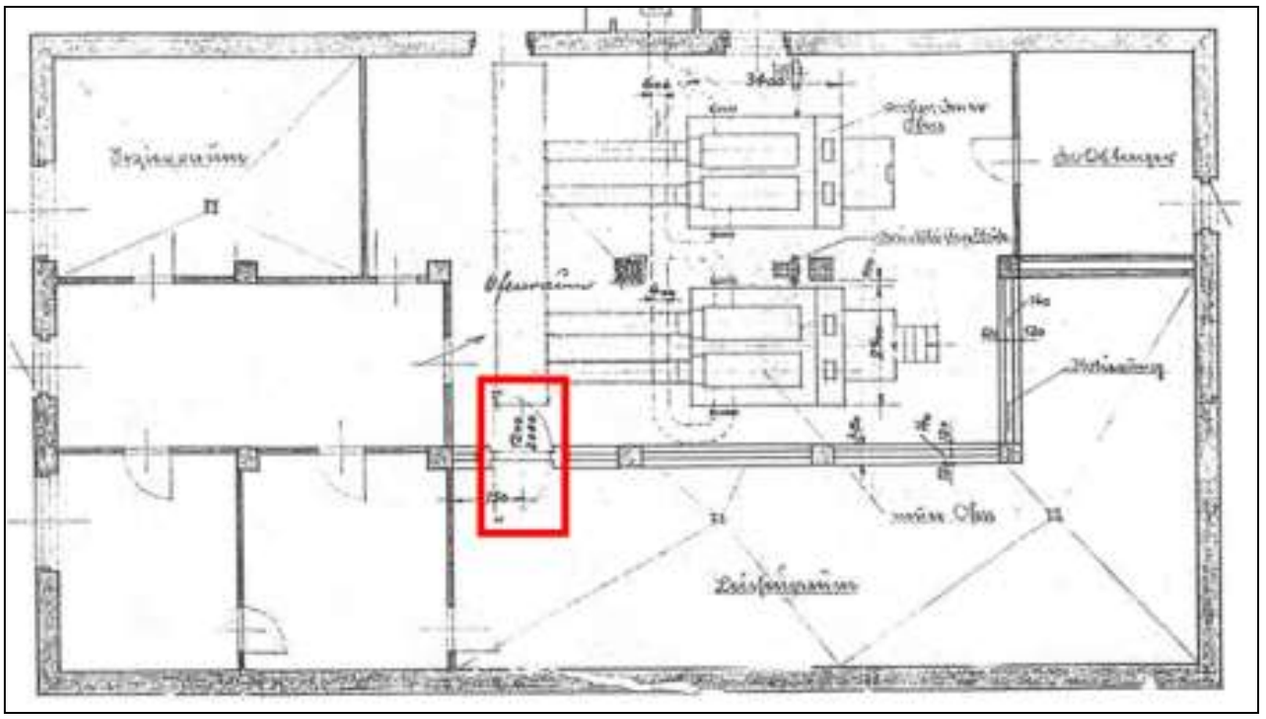

Figure 19: SS blueprint of Crematorium I drawn on November 30, 1940 clearly showing a swing door (inside added rectangle) between the morgue (bottom) and the furnace room (top). See section enlargement in Figure 19a.

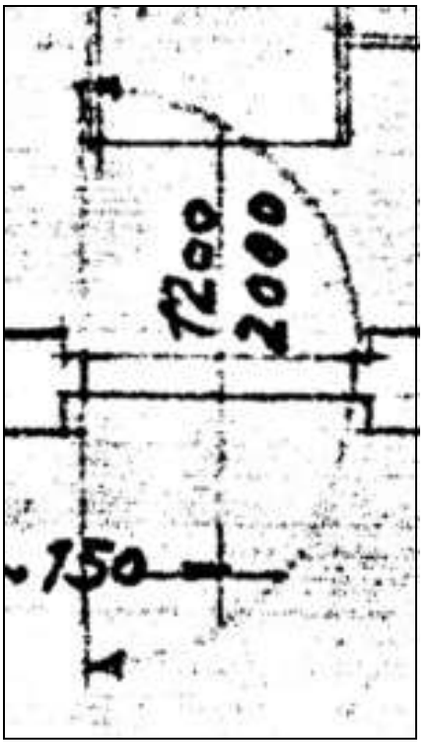

Figure 19a: Section enlargement of Figure 19.

Such a swing door, quite like doors commonly seen in restaurants, leading to the kitchen, was very convenient for crematorium workers whose hands were tied up carrying corpses – or corpse stretchers with corpses – from the morgue to the furnace room. Their hands tied up holding their heavy load, they could easily push open the door when approaching it, and the door would also automatically close behind them, thus preventing too much warm air from getting from the furnace room into the morgue.

A door designed to open in both directions is utterly worthless as a gas-tight homicidal-gas-chamber door, however. Such a swing door could not be properly braced against dozens of panicking gassing victims attempting to bash down the door. More importantly, a swing door of this type would by necessity contain a large gap between the door and the door frame to allow such a swinging action to occur. Such a door would also have gaps above and below the door. These big gaps mean that this swing door could not be gas-tight whatsoever, rendering it unfit for use in a location where large amounts of poison gas are said to have been used.

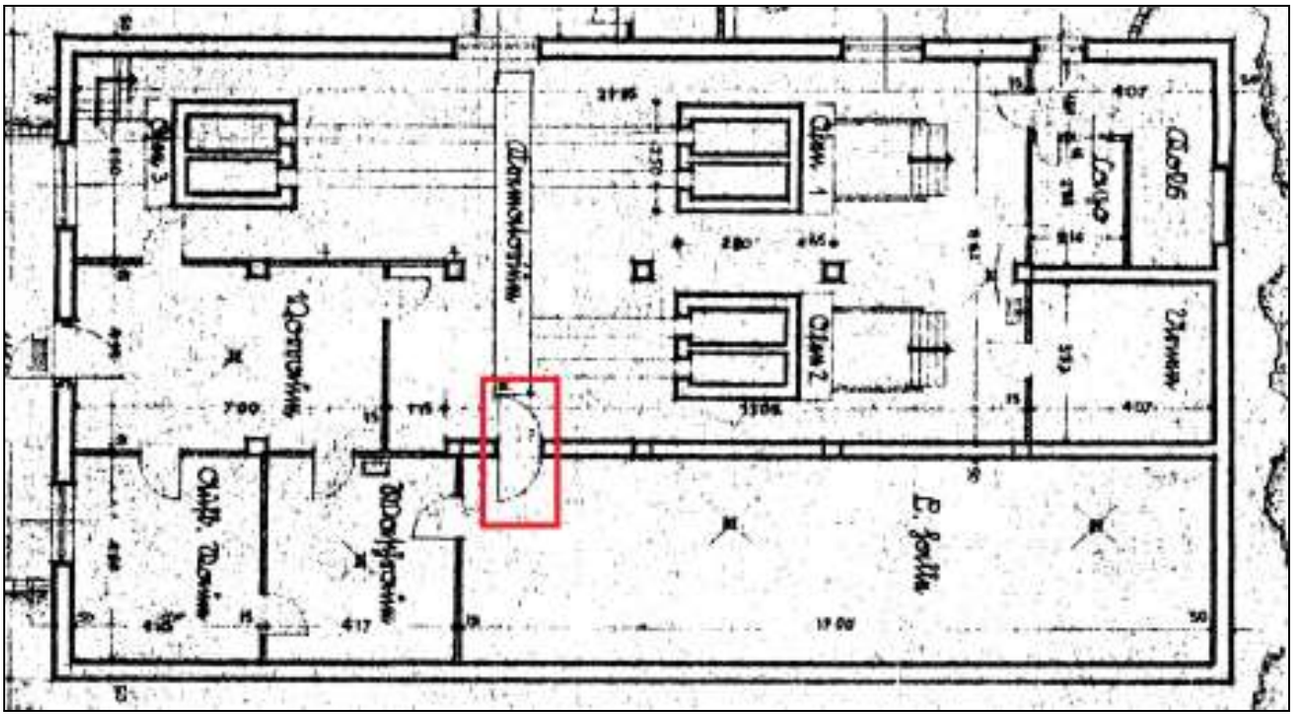

Figure 20: SS blueprint of Crematorium I drawn on April 10, 1942, while the morgue was allegedly being used as a homicidal "gas chamber," again clearly showing a swing door between the morgue (bottom, inside added rectangle) and the furnace room (top). See section enlargement in Figure 20a. (Source: RGVA, 502-2-146, p. 21)

Evidence of this swing door existing unmodified inside Crematorium I before, during, and after homicidal gassings are said to have occurred there is additional strong evidence against the museum's current homicidal-gas-chamber claims.

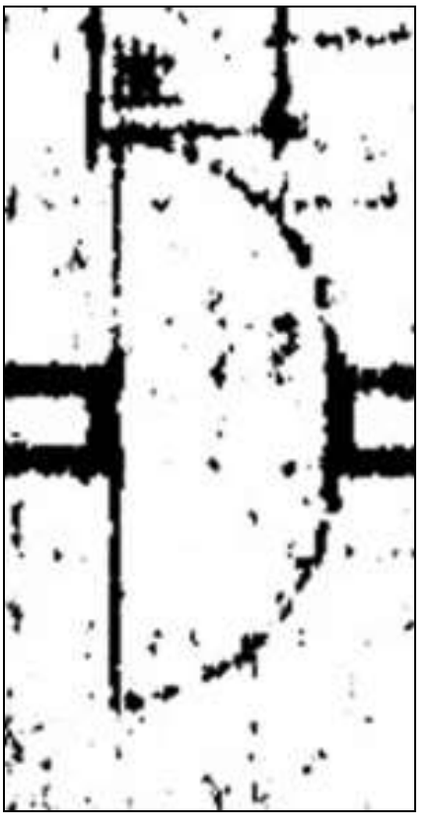

Figure 20a: Section enlargement of Figure 20.

It is conceivable that what we see in those blueprints actually consists not of *one* swing door but of two doors, one opening into the morgue, the other into the furnace room. Although possible and well-suited for thermal insulation, such a layout would be cumbersome to deal with for moving corpses to and fro. What matters in the present context, however, is that a door opening *into* the morgue could not have been opened up if hundreds of corpses had piled up in the morgue after a claimed gassing, because when suffocating, people tend to congregate near doors, hence they pile up and die in front of them. So either way, that door design as shown on the blueprints was no good for a homicidal gas chamber.

While these blueprints prove that they do not reflect any outfitting of the morgue for homicidal purposes, it can be argued that such deception was in fact intentional, meaning that the floor plans were simply not updated in this

regard, in particular regarding the swing door, in order to conceal the criminal changes made. Maintaining this argument becomes close to impossible, however, if we consider the other door in that room.

The Door between Morgue and Washroom

What remains to be discussed is the door which separated the former washroom from the morgue/"gas chamber". Since that wall was removed in 1947 during "reconstruction," all we have is again war-time blueprints.

In a long 1998 article, German architect Willy Wallwey, writing under the pen names of Hans Jürgen Nowak and Werner Rademacher, summarized what the extant documentation accessible in various Moscow archives reveals about gas-tight doors offered to, delivered to and installed in the various buildings at Auschwitz. Wallwey concluded that the Auschwitz camp authorities did indeed request cost estimates for sturdy, gas-tight, and probably also panic-proof steel doors, but they were never delivered. These doors even had so-called wedge locks used to close them in an air-tight fashion, a closing mechanism that could be called "screwing" the doors shut as described by witnesses, see Figures 21f.[10]

The two existing air-raid-shelter doors made for Krematorium I in 1944 during the building's conversion to an air-raid shelter are made

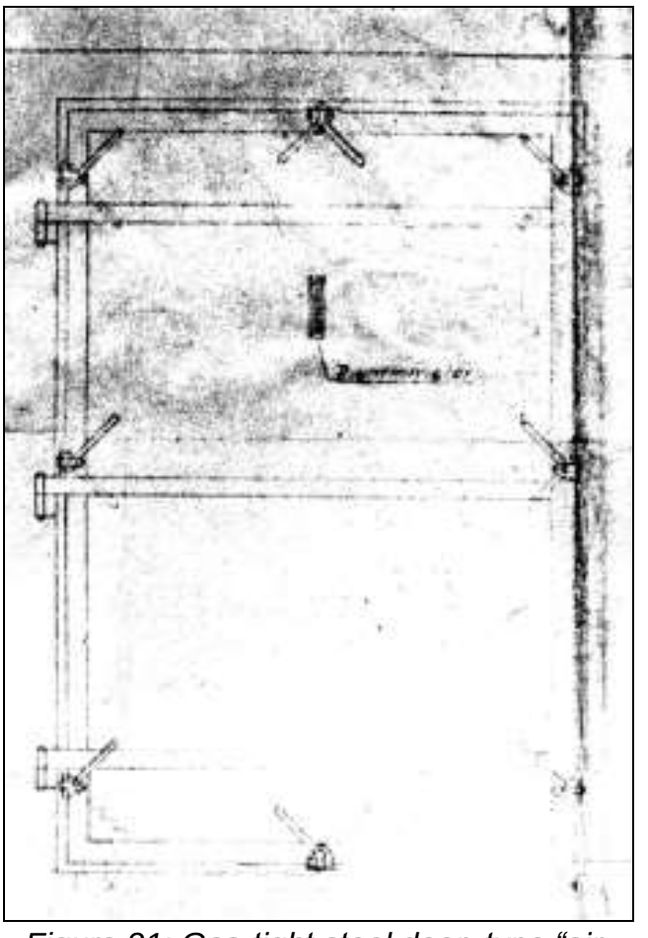

Figure 21: Gas-tight steel door, type "air-raid shelter", offered to the Auschwitz Camp, but never delivered.

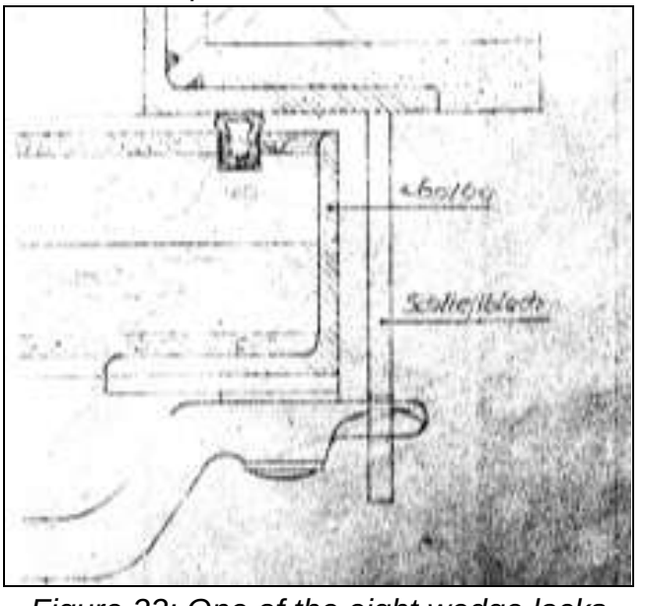

Figure 22: One of the eight wedge locks of a gas-tight steel door, type "air-raid shelter", offered to the Auschwitz Camp, but never delivered. The wedging of these levers into the lock position could rightly be called "screwed shut".

[10] RGVA 502-1-354-8; July 9, 1942; see Rudolf 2019, p. 326.

of wooden planks covered by thin sheet metal, see Figure 23. Although these doors were probably built by the local inmate workshop, so far no documentation about them has been found. This proves that not everything that was constructed at the Auschwitz Camp left a trace in the documental record, or if it did, it didn't survive. Hence, it is conceivable that sturdy gas-tight doors similar to those shown in Figures 21f. were in fact delivered to Auschwitz and were subsequently installed there without leaving a documental trace.

Figure 23: Makeshift air-raid-shelter door of Krematorium I made of wood with a thin sheet-metal cover, probably built by inmates in the camp's workshop.

While it cannot be ruled out categorically that panic-proof, gas-tight steel doors were indeed delivered to Auschwitz and may have been installed elsewhere, it can be ruled out, based on war-time floor plans, that any such door could have been installed in the relevant door openings of the morgue of Krematorium I.

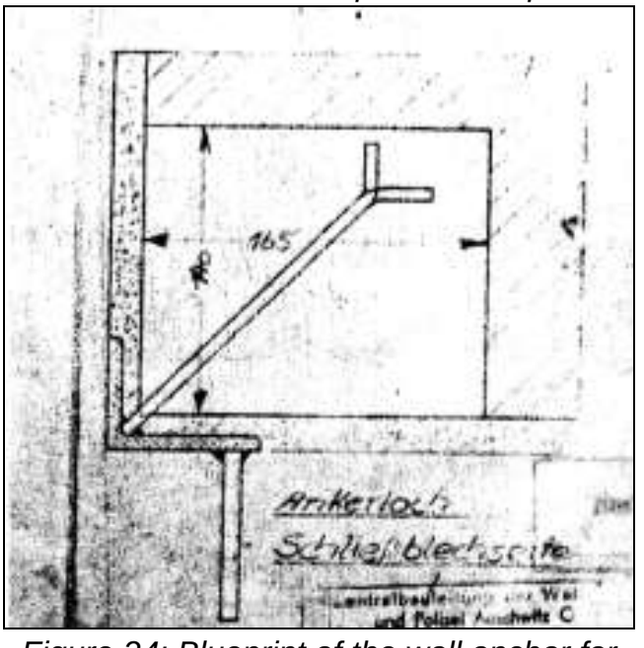

Figure 24: Blueprint of the wall anchor for a frame of a sturdy, gas-tight steel door.

First, we need to be aware that the frame of a massive wooden or even a steel door designed to withstand a panicking crowd needs to be anchored firmly in the wall. Figure 24 shows a hoop steel anchor with a so-called dovetail going some 14 cm (5.5 inches) into the wall.[10] Needless to say, the wall itself had to be considerably thicker than 14 cm in order to firmly accommodate such an anchor.

Turning to the war-time floor plans of this morgue, we see that the wall separating the morgue from the adjacent washroom and the wall separating the morgue from the furnace room were both very thin: 15 cm, which is the width of a standard brick plus some plaster on both sides of it

(see Figure 25). Hence, these walls consisted only of one row of bricks set lengthwise. The wall separating the morgue from the furnace room consisted of two such walls with a gap of some 30 cm in between (for thermal insulation).[11]

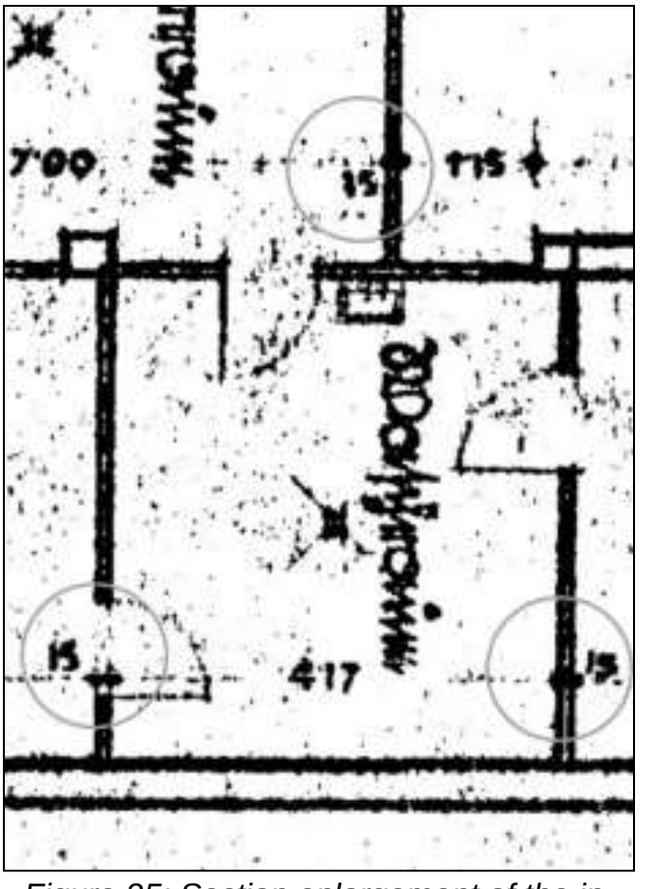

Figure 25: Section enlargement of the inventory plan of Krematorium I from Figure 20, showing the washroom with adjacent walls with grey circles added to highlight the walls' width of 15 cm.

It is not possible to set a steel anchor into bricks. In such a case, bricks have to be removed, and then the anchor placed into a block of cement/concrete. However, since these walls consisted only of one row of bricks – unless they consisted only of a wooden framework of 2-by-5s plus some boards, in which case we need no longer discuss this issue – removing a brick to place an anchor embedded in cement in its stead would have left this chunk of cement held in place by nothing more than the bricks on top and at the bottom of it. Such a chunk would have become loose very quickly. Any forceful shaking of the door would have dislodged those anchors, bent the frame, and made the frame including the door fall out of the wall sooner or later.

In other words, the meager thickness of these walls proves that no sturdy, panic-proof door of any kind could have been installed in them.

The only option left for the traditionalists is to claim that these walls were reinforced to a much thicker width at the very moment the morgue is said to have been converted into a homicidal gas chamber, meaning in September 1941. Yet evidence for this exists neither in the documental record nor in witness testimonies known to me.

As the late Dr. Robert Faurisson put it aptly:

"No doors, no destruction."

[11] This reveals a flaw in the 3-D drawings shown in Illustrations 4f. depicting the internal walls prior to the conversions to an air-raid shelter. These walls were much thinner than depicted in these drawings.

Dear Sir

In response to the letter from 14 March, I would like inform that unfortunately we can not help you. Our museum does not have any documents on matters that interest you.
From the memories of former employees (very often ex-prisoners) we know that the work on the reconstruction of furnaces, chimney etc., made in the second half of 1947.

Best regards

dr Igor Bartosik

Letter by Dr. Igor Bartosik, head of the Auschwitz Museum's Research Center, confirming the lack of any documentation about the condition of Crematorium I at war's end and any subsequent alterations.

Part Two:

How the

Auschwitz Museum

Lies about Documents

in Its Archives

Introduction

In 2014 the Auschwitz Museum published a bilingual (Polish and English)[12] book edited by Igor Bartosik, Łukasz Martyniak and Piotr Setkiewicz titled *The Beginnings of the Extermination of Jews in KL Auschwitz in the Light of the Source Materials*. I subsequently give the page numbers in parentheses.

Right at the beginning of the book, in its introduction, it contains a clumsy attempt at disinformation:

> *"For many years, the beginning of the extermination of Jews in the gas chambers has been one of the least-researched issues in the extensive literature on the history of KL Auschwitz. Numerous monumental works by historians devote only a few pages to the question."* (p. 23)

A footnote refers to:

> *"Franciszek Piper,* The Bunkers – Temporary Gas Chambers in Auschwitz 1940-1945 *(Oświęcim, 2000), vol. III, pp. 134-143; Jean-Claude Pressac,* Technique and Operation of the Gas Chambers *(New York, 1989), pp. 161-182; Robert Jan van Pelt,* The Case for Auschwitz *(Bloomington, 2002), pp. 72, 180."*

The authors can only speak for themselves and for other orthodox historians. As they know well but prefer to hush up, I have written three studies on this topic of together almost 600 pages:

– *Auschwitz: la prima gasazione*. Edizioni di Ar, Padua, 1992; most recent English translation: *Auschwitz: The First Gassing. Rumor and Reality*. 3rd ed., Castle Hill Publishers, Uckfield, 2016, 190 pp., 15 documents and 33 photographs;
– *Auschwitz: Crematorium I and the Alleged Homicidal Gassing.* Theses & Dissertations Press, Chicago, 2005, 138 pages, 35 documents; 2nd ed., Castle Hill Publishers, Uckfield, 2016;
– *Debunking the Bunkers of Auschwitz: Black Propaganda versus History.* Most recent edition: Castle Hill Publishers, Uckfield 2016, 264 pp., 26+7 documents and 21 photographs.

The authors explain this lack of attention by orthodox Holocaust historiography mainly by "the lack of source materials, basically limited to collections of accounts, memoirs, and testimony delivered during the trials of Nazi criminals following the end of the war." But that changed, as they explain:

> *"Only at the beginning of the 1990s, with the declassification of the records of the SS Central Construction Board that had been held until then in*

[12] In the present study I rely on the English text, but in case of necessity fall back on the Polish version.

> *Moscow, did it become possible to access German documentation making it possible to fill in to a considerable degree the historical knowledge about the functioning of the first gas chambers in Auschwitz."* (p. 23)

All this documentation has finally been cataloged and studied by historians of the Auschwitz Museum:

> *"As a result of extensive searches conducted in both the Zentralbauleitung collection and the other archival resources, a range of interesting and previously unknown documents has been identified."* (p. 24)

This implied claim of historical discovery is disingenuous, since of the 74 documents published by them, I had already published nine, Pressac had published three, and another 19 had previously been mentioned and discussed by me.

The authors have divided these documents into six sections (p. 24):

1. "the history of the gas chambers at crematorium I in the Auschwitz I camp": Documents 1-7. The title of this chapter is "The crematorium and gas chamber in the Auschwitz I Main Camp" (p. 41).
2. "the functioning of the provisional gas chambers in Birkenau, known as bunkers I and II ('The Little Red House' and 'Little White House')": Documents 8-20. Chapter title: "Provisional gas chamber bunkers I and II in Birkenau" (p. 63).
3. "the wooden barracks used as undressing rooms for the people murdered in bunkers I and II": Documents 21-42. Chapter title: "The barracks for undressing at bunkers I and II" (p. 103).
4. "the history of the unloading ramp where Jews deported to Auschwitz underwent selection": Documents 43-51. Chapter title: "The railroad ramp (Alte Judenrampe)" (p. 173).
5. "the establishment of the Sonderkommando and its first year of existence": Documents 52-58. Chapter title: "The Sonderkommando" (p. 199).
6. "the mass murders, known as 'special operations,' carried out in the camp": Documents 59-74. Chapter title: "Sonderaktionen (Special operations)" (p. 215).

Excluding the nine documents on the "*Judenrampe*," which are insignificant for the Holocaust, 31 of the 65 documents, almost half of them, are not new at all.

I will defer a detailed examination of the authors' "Introduction" to Part Two of this present study, because only after a critical analysis of the documents cited in their book will the reader be able to full understand my critical examination of the authors' allegations.

Note on references to Documents

When referring to documents reproduced in the Appendix to this present study, the word DOCUMENT is set in SMALL CAPS. In all other cases, where another authors' documents are referred to, they are set in plain text.

Chapter One: The Documents – Critical Comments

I. Section "The Crematorium and Gas Chamber in the Auschwitz I Main Camp"

[1] Document 1 (p. 43)

This is a letter by the head of the Main Office Budget and Construction (*Der Chef des Hauptamtes Haushalt und Bauten*) of 4 June 1940, with the subject "Camp Occupancy" ("*Belegstärke*"), addressed to the SS New Construction Office (SS-*Neubauleitung*) Auschwitz. The text merely states:

> *"According to a communication by SS*-Oberführer *Glücks of June 1,* [19]*40, the Auschwitz camp is to be expanded in such a way that it will later be able to accommodate 30,000 inmates and a guard detail of 6 companies."* (p. 43)

The authors comment on this as follows:

> *"This document thus attests that even in mid-1940 plans for the significant expansion of KL Auschwitz were in existence. This would make the planned camp the largest one in the Third Reich, capable of holding more prisoners than all the concentration camps then in existence combined."* (p. 42)

In the context of the examined section, this documents is absolutely irrelevant, for it refers neither to a crematorium nor to an alleged "gas chamber" at the Auschwitz Camp. It would have made more sense to refer here to other documents, like for instance to the budget for the Auschwitz Camp as drafted by SS-*Obersturmführer* Fritz August Seidler on 30 April 1940, which provides for the construction of a new crematorium ("*Neubau Krematorium*") at a cost of 15,000 RM.[13]

The authors also ignore that the "Report of Office II – Constructions of the Main Office Budget and Construction for 1941" ("*Bericht des Amtes II – Bauten des Hauptamtes Haushalt und Bauten im Jahre 1941*") provided for the construction of a camp at Lublin and another one at Auschwitz for 150,000 prisoners of war,[14] which means that no particular priority or importance can be attributed to the latter.

[2] Document 2 (p. 45)

This is an "Activity Report" ("*Tätigkeitsbericht*") of June 20, 1940, for the period of June 14-20.

---

[13] "Kostenaufstellung für das Lager Auschwitz bei Kattowitz." RGVA, 502-1-176, p. 37. See Mattogno/Deana, vol. I, p. 212.

[14] RGVA, 502-1-13, p. 4.

The authors highlight the final lines of the document:

> *"The situation maps were compiled for the projected SS barracks building, and the implementation of the development for the new state of construction was commenced. The preliminary drafts for a new crematorium building were developed and finalized."* (p. 45)

The authors briefly summarize this passage and add that this crematorium made

> *"*[…] *Auschwitz the first German concentration camp in which – surely because a high future death rate was envisioned – a stationary installation for burning the bodies of prisoners was planned from the moment of its founding."* (p. 44)

This is a simple insinuation denying the fact that, as early as 18 June *1938*, and with respect to the *Buchenwald* concentration camp, a request for an "emergency crematorium" (*Notkrematorium*) was presented to SS-*Gruppenführer* Theodor Eicke, who at that time was the head of the SS-*Totenkopfverbände* (Death's Head Units) and of the German concentration camps. On 21 December 1939, the Topf & Söhne company of Erfurt, Germany, which had been approached by the SS authorities in this regard, submitted a cost estimate for "1 Topf incineration furnace, oil- or coke-fired, with double muffle and compressed air unit, as well as a draft enhancing unit" ("*1 öl- oder koksbeheizter Topf-Einäscherungs-Ofen mit Doppelmuffel und Druckluft-Anlage, sowie Zugverstärkungs-Anlage*"), drawing D 56570 "double-muffle cremation furnace with oil-firing" (*Doppelmuffel-Einäscherungsofen mit Ölfeuerung*) and an undated drawing with the headline "Crematorium of the Bu. CC" ("*Krematorium des K.L. Bu*.") featuring the blueprint of that crematorium.[15]

The comment of the authors is clearly specious, because during the period when the crematorium was requested, the Buchenwald camp had merely 7,958 detainees (7 August 1938; Kommunistische…, p. 30).

The "Description of the structure of the new emergency crematorium building in the camp for detainees of Buchenwald concentration camp," written on 10 January 1940 by the New Construction Office at Buchenwald, states in this respect (NO-4401; cf. Mattogno/Deana, p. 208):

> *"On account of the high mortality at the Buchenwald concentration camp, the need has arisen for the construction of an emergency crematorium with a furnace (double-muffle furnace) heated by oil."*

If the SS provided a crematorium for a concentration camp containing less than 8,000 detainees, how can we be surprised that they had contemplated one for a camp designed for 30,000 inmates? The authors' reference to "a high future death rate" at Auschwitz is thus at least malicious. It is obvious that the

---

[15] Cf. Mattogno/Deana, vol. I, pp. 208-212, vol. II, Documents 171-174, pp. 275-284.

SS's decision to build a crematorium at Auschwitz was based on their own experience at the Buchenwald camp.

This document therefore does not represent anything new. As for me, I mentioned this in my study of the Auschwitz cremation furnaces as follows:[16]

> *"Instead of erecting a new building, however, the equipment was eventually installed in a bunker of the former Polish artillery barracks which constituted the nucleus of the new concentration camp. The plans for the crematorium were drawn up in the week of 14 to 20 June* [1940]*."*

[3] Document 3 (pp. 47f.)

This is another Activity Report, dated 19 July 1941 for the period of 14-19 July, as the headline of this document states on its first page, which the authors omitted ("*Tätigkeitsbericht vom 14. bis 19.7.1941*").[17] Paragraph IV on page III, headlined "Planning" ("*Planung*"), states:

> *"SS*-O[ber]scha[*rführer*]. *Maier of Office II Berlin delivers preliminary drafts for the headquarters building. Revising of the draft for a delousing facility with hydrogen cyanide system. Discussion with Camp Commander, Head of Administration, First Leader of Protective Custody Camp and Head of the Pol.*[itical] *Dept. concerning space requirement of the project."*

This absolutely innocuous document is interpreted by the authors as follows:

> *"The point 'IV – Planning' notes a visit by SS-Oberscharführer Maier, a representative of Department II of the SS-WVHA. He took part in a meeting during which plans for a disinfection installation using Zyklon B (*Blausäure – System*) were discussed. The highly unusual presence of the head of the Politische Abteilung, Maksymilian* [recte: Maximilian] *Grabner, at a meeting on construction work is noteworthy. Two months later, Lagerführer Karl Fritzsch—present at the July meeting—made the decision to use Zyklon B to murder several hundred Soviet POWs and sick prisoners in the cellars of block 11. It seems certain* [*przyjąć zapewne należy* = must certainly assume] *that he did so after conferring with Grabner, at a time when commandant Höss was absent.*
>
> *The use of Zyklon B in Auschwitz for sanitary purposes made it possible to train a group of SS disinfectors who, having acquired this experience, could next be assigned to operate the gas chambers."* (p. 46)

This comment is a masterpiece of disinformation and hypocrisy; it aims in a childish manner at creating a predicate offense in order to somehow substantiate the mythical "first gassing" in the basement of Block 11 at the Auschwitz

---

[16] *Ibid.*, p. 212, with the archival reference to the activity report (*Tätigkeitsbericht*) dated 20 June 1940, for the period of 14-20 June. RGVA, 502-1-214, p. 102.

[17] RGVA, 502-1-214, p. 22.

Main Camp. The attempt, however, is rather clumsy: first the authors arbitrarily assign an exceptional character to Grabner's presence at a meeting which he was fully entitled to attend as set out in the document itself; then they presuppose the historical reality of the "first gassing," in support of which they do not, of course, submit any "new document"; finally, they establish a fictitious connection between these two assumed events, insinuating that Fritzsch had consulted with Grabner prior to this "gassing." The comment implies that Grabner insinuated himself into a matter which was none of his business – a disinfestation facility using hydrogen cyanide – allegedly due to malicious homicidal intentions; next Grabner is said to have suggested to Fritzsch to use hydrogen cyanide in order to kill Soviet prisoners of war and detainees, an advice which Fritzsch allegedly implemented. This way they invent a "documentary confirmation" of the "first gassing," the one being as inconsistent as the other!

The specious character of the documentary reference cited by the authors is even more evident when considering that, in the same series of reports, the disinfestation of buildings is mentioned twice prior to 19 July 1941, once even in the report of 12 July 1941, which immediately predates the one discussed above:

> *"Building No. 54 meant to accommodate the guard detail was gassed against vermin and diseases."*[18]
>
> *"Completion of mounting sinks and toilets in Block 14; further work was impossible, as* [the building was] *completely occupied due to gassing of Block 16."*[19]

That the SS disinfestors, who had attended special training course on the use of Zyklon B, were later deployed to carry out the alleged homicidal gassings, is yet another fable invented by the authors.

[4] Document 4 (p. 51).

This is a list dated 1 December 1941 bearing the title "Consumables. Deliveries during November 1941. – from 1 Nov. to 30 Nov." ("*Verbrauchsmittel. Eingang im Monat November 1941. - vom 1.11.-30.11.*"). Among others, it also contains the following entry: "3000 (kg) of Zyklon (hydrogen cyanide) railroad car Munich 19931 – Dessau" ("*3000 (kg) Zyklon (Blausäure) Wagg. Münch. 19931 - Dessau*"; p. 51). This is the authors' explanation:

> *"The document notes the delivery to the camp of three tons of Zyklon B from Dessau. Lists of this kind for 1941 are only partially extant; this document is the first one recording the delivery of Zyklon B to the camp. It is*

[18] *Tätigkeitsbericht* of 12 July 1940. RGVA, 502-1-214, p. 97.
[19] *Tätigkeitsbericht* of 12 July 1941. RGVA, 502-1-214, p. 25.

> *evident that, because Zyklon B was used in September of that year to murder Soviet POWs, there must also have been earlier deliveries."* (p. 50)

It is a complete mystery what relationship this document has with the crematorium and the alleged "gas chamber" of the Auschwitz Main Camp. Instead, the authors' malicious intent is blatantly clear: they try to consolidate a purely imaginary event by conflating it with a real but chronologically unrelated fact. Their convoluted reasoning is that, since 3,000 kg of Zyklon B were supplied on 1 December 1941, there must also have been earlier deliveries, because Zyklon B was used in September 1941 for the "first gassing," hence this document "confirms" that imaginary event! This is a puerile sophism. What can be said – even though it is tautological but at least serious – is that there must have been earlier supplies of Zyklon B, because at least the two above-mentioned documented disinfestation gassings were carried out in that camp prior to December 1941.

[5] Document 5 (p. 53)

This is a work report (*Arbeitskarte*) of the inmate locksmith shop (*Häftlings–Schlosserei*) for the crematorium at Auschwitz dated 25 September 1941 with the subject of manufacturing four airtight flaps (*Luftdichte–Klappen*). The authors comment on this document as follows:

> *"In the autumn of 1941, the camp authorities began killing prisoners with Zyklon B gas. After the murder of a group of Soviet POWs and sick prisoners in the basement of block 11 in early September 1941, the room in the crematorium I building that had previously served as a morgue was designated as a gas chamber. In order to seal the space to the extent required, airtight doors were installed and openings were made in the ceiling for the introduction (pouring in) of Zyklon B; these openings were sealed off by the flaps mentioned in the document."* (p. 52)

Here they completely change the meaning of the document. For starters, the adjective "*luftdicht*," meaning "airtight" and properly translated as such in the English text, was changed to "*hermetyczny*" (hermetical) in the Polish text, which is a generic term which can apply both to a possible "gas chamber" and to a ventilation system, while the proper term for a gas chamber (or gas shelter, for that matter) would be "*gasdicht*" (gas-tight).

The historical and documentary context of this document points to a ventilation system for the crematorium's morgue. The document in question is neither new nor unpublished, because I reproduced it in 2005 along with its reverse side, which the authors' did not reproduce (Mattogno 2005a, pp. 120f.), and I thoroughly discussed its meaning and context (*ibid*., pp. 19-21), which I will reiterate here.

On June 7, 1941, SS-*Untersturmführer* Maximilian Grabner, head of the Auschwitz Political Department, wrote the following letter to the SS-*Neubauleitung*:[20]

> *"It is absolutely necessary to install a separate ventilation in the morgue of the crematorium. The existing ventilation has been rendered useless by the installation of the second furnace. When the second furnace is in use – and that is now the case almost daily – the ventilation flap to the morgue has to be closed because warm air otherwise enters the morgue, causing the exact opposite of a ventilation.*
>
> *The deficiencies of the ventilation and of the fresh air feed are particularly noticeable under the prevailing conditions of warm weather. It is hardly possible to spend any time in the morgue, even if such instances are generally of short duration.*
>
> *A proper ventilation will surely lead to an improvement in the quality of the air and to a reduction of the humidity of the room. It would also do away with the presence of flies in the morgue or at least reduce this nuisance to a minimum. The elimination of such deficiencies is in the general interest, not least because it would put a stop to the spread of disease by the flies.*
>
> *It is therefore requested that two ventilators be installed in the morgue, one for intake and one for exhaust. A separate duct leading to the chimney must be provided for the exhaust. It is requested that the work be started as soon as possible."*

Between the end of September and the middle of October 1941, ventilation work, which certainly stemmed from Grabner's complaints, was carried out in the crematorium. A "work report" of the inmate locksmith shop dated September 25, 1941, mentions the following order: "Make 4 air-tight flaps." The work was done the same day by the detainees Zalewski (8363), Morgiel (7686), and Dudziński (16197), blacksmiths, and Bialas (1461), welder, in a total of 11 man-hours. As is noted on the back of the sheet, the 4 flaps were done in black plate (*Schwarzblech*).[21]

Another work report of the inmate locksmith shop for the crematorium, dated 7 October 1941,[22] refers to "fabrication of 2 ventilation caps in steel plate with an internal space of 27×27 cm, otherwise according to instructions." The work was done by the detainee welder Bialas and the detainee plumbers Maliszewski (9612) and Dyntar (1409) in a total of 50 man-hours between 7

---

[20] RGVA, 502-1-312, p. 111.

[21] "*4 St. Luftdichte–Klappen anfertigen*," RGVA, 502-2-1, pp. 74-74a.

[22] The date refers to the receipt of the order.

and 13 October 1941. For the fabrication of these devices, 4 square meters of black plate were used.[23]

The "airtight flaps" were the air-tight closures which served to block off the ducts of a room from the system of ventilation. The "ventilation caps" were probably vertical tubes with caps to block off (or keep rain out of) vent stacks such as those (in brickwork) which were erected on the roof of the crematorium above the two furnaces for the ventilation of the furnace room.

The "Inventory map of building No. 47a, *BW*[24] 11. Crematorium," drawn on 10 April 1942 by detainee 20033 (the Polish engineer Stefan Swiszczowski), shows in its view of the chimney on the flat roof, to the left, a fat angled tube, which probably housed an intake fan (*Belüftung*).[25] It could not have been an exhaust fan (*Entlüftung*), or a duct for exhaust air for two reasons: first of all, for the evacuation of the waste air from the morgue Topf had proposed a chimney 10 meters high, whereas the SS-*Neubauleitung*, for reasons of economy, had opted for the use of the existing chimney. Both Topf and SS-*Neubauleitung* were in agreement that the air removed from an ordinary morgue would have to be discharged at least 10 meters above ground. In that case, how could SS-*Neubauleitung* have decided to discharge not only the waste air from the morgue but even the lethal exhaust from the alleged homicidal gas chamber through a duct no more than 5 feet high?[26]

Secondly, blowing out the waste air through the duct in question would have necessitated opening one or both doors of the morgue – not a good solution hygienically for an ordinary morgue, and highly hazardous for a homicidal gas chamber.

Hence, if an intake fan had been housed in that duct, the ventilation of the morgue could only have been of the type requested by Grabner. The ventilation system of the morgue was connected, through a metal duct, to the air conduit that passed under the floor of the furnace room and went to the chimney. Upstream of the juncture with the chimney there was an exhaust fan.

Such an arrangement, however, could only have functioned up to the beginning of July 1942, when the old chimney of the crematorium was demolished. No air conduit was, in fact, attached to the new chimney, as is evident from the corresponding design drawing done by the Köhler company on 11 August 1942 regarding a "Smoke flue for the Central Construction Office of the Waffen–SS and Police Auschwitz, O.S."[27]

---

[23] "*Anfertigen von 2 Stück Entlüftungshüten aus Eisenblech 27/27 cm i. L. sonst nach Angabe*," RGVA, 502-2-1, pp. 75-75a.

[24] *Bauwerk* – building or construction site with multiple buildings of the same type; the term designated also administrative acts.

[25] "*Bestandplan des Gebäudes Nr. 47a. B.W. 11. Krematorium*," RGVA, 502-2-146, p. 21.

[26] This was Jean-Claude Pressac's hypothesis.

[27] "*Rauchkanal für die Zentralbauleitung der Waffen–SS und Polizei Auschwitz O.S.*", RGVA, 502-2-23, p. 18.

The authors avoid any reference to the work report of 7 October 1941, apparently because it refers very explicitly to a ventilation system, which would have compromised their bogus interpretation of the work report of 25 September in terms of those flaps being destined to equip a homicidal gas chamber.

[6] Document 6 (pp. 55f.)

This is an "Activity Report for the month of May 1942" ("*Tätigkeitsbericht für den Monat Mai 1942*") written by *Sturmmann* Heinz Lubitz on 30 May 1942, which I mentioned in my study of the Auschwitz Central Construction Office (1998, p. 40; 2005d, p. 34) and in more detail in my study of the Auschwitz cremation furnaces. Paragraph 13 on page 2 says:

> *"Crematorium. Removal of the old cobbled pavement. Erecting a concrete fence in front of the entrance with 2 entry gates. Redoing the new driveway with cobblestones. Transport of material. Removal of soil."* (p. 56)

The authors' comment reveals an extremely far-fetched logic:

> *"Deportees undressed in the yard thus formed before entering the gas chamber."* (p. 54)

There exists quite obviously not the slightest documentary connection between these activities and the alleged "gas chamber" of Crematorium I. This is therefore a crude attempt to indirectly substantiate this "gas chamber" with a document which is absolutely meaningless in the context of the orthodox Holocaust narrative.

As I mentioned above, the document in question does not represent anything new. In 2012 I summed up this document as follows (2012, Vol. I, p. 265; Mattogno/Deana 2015, Vol. 1, p. 221):

> *"During the latter half of May, work on the exterior was carried out: the yard in front of the crematorium was fenced in and provided with two wooden gates, the old pavement was replaced."*

In Footnote 173 (208 of the English edition) I gave as sources:

> "Zentralbauleitung, Auftrag Nr. 436, Arbeitskarte Nr. 20 *for* Tischlerei *dated 13 May 1942: manufacture of two entrance gates (*Einfahrttoren*) 4 × 3.20 m, work done between 21 and 25 May. RGVA, 502-2-1, p. 24. Description of the job:* Tätigkeitsbericht für den Monat Mai 1942, *RGVA, 502-1-24, p. 299, and* Baubericht für Monat Mai 1942, *RGVA, 502-1-24, p. 261."*

The authors do not mention the other two documents adduced by me.

[7] Document 7 (pp. 59-61)

This is a "List of structures under construction with extent of completion." On p. 3 under no. 28, we find the following text: "Construction of a gas-tight treatment room in the former crema. for the garrison physician."

The authors explain that this refers to the "conversion[28] of an existing gas-tight room in the former crematorium I [*eines gasdichten Behandlungsraumes im früheren Krema*] for use by the garrison physician." They then add that the "furnaces in the crematorium were dismantled in 1944; the room used as a gas chamber was to be adapted as an air-raid shelter for the nearby SS hospital." (p. 58).

This interpretation completely distorts the significance of this document, which has been known for many years and which I already mentioned in my 2005 study on the "gas chamber" in Crematorium I. Since this book appeared in both English and German, I reiterate the text of Chapter II.2. headed "The Transformation of Crematorium I into an Air-Raid Shelter" (2005a, pp. 22-24).

On 16 November 1943, the commander of the Auschwitz Camp, SS-*Obersturmbannführer* Liebehenschel, issued the following order regarding "Air-raid measures at Garrison Auschwitz":[29]

> *"Upon advice of the competent superior authorities, the necessary air-raid protection measures will now also be undertaken in the Auschwitz garrison area with immediate effect. In my capacity as local air-raid-protection officer I have appointed SS*-Untersturmführer *Josten to be my permanent representative. I request all services to support SS*-Untersturmführer *Josten in every possible way."*

The order became effective as of 1 January 1944.[30] According to the usual practice, a construction site was defined for this purpose: *BW* 98, "air-raid shelter trench," into which all such shelters planned or eventually built at Auschwitz were integrated. They became sections of *BW* 98 and carried the same designation, with an added letter. For example, the air-raid shelter of the camp commander's residence became *BW* 98J. The old crematorium at Auschwitz also became part of this system of air-raid-protection measures.

On 16 July 1944, during his visit to Auschwitz, SS-*Obergruppenführer* Pohl approved the "Installation of a gas-proof operating room and shrapnel-proof shelter in the former crematorium for the garrison surgeon," which became *BW* 98M.[31]

On 26 August 1944, Josten, who had meanwhile been promoted to SS-*Obersturmführer* and appointed "head of air-raid protection" ("*Luftschutzlei-*

> *16 pcs. window shutters, gas-tight and shrapnel-proof*
> *7 pcs. doors, gas-tight and shrapnel-proof"*

On 17 October SS-*Sturmbannführer* Bischoff[33] wrote a letter to the Central Construction Office regarding the start of work, which "due to urgency," could begin immediately without the usual bureaucratic formalities.[31] The work had, however, already started. A document dated 4 September mentions

---

[32] RGVA, 502-1-401, p. 34.

[33] On 1 October 1941 Bischoff, at that time *SS-Hauptsturmführer*, replaced *SS-Oberscharführer* August Schlachter as head of the Auschwitz *Bauleitung*, whose name was changed to *Zentralbauleitung* on 4 November 1941. On 1 October 1943 Bischoff, who was replaced by *SS-Obersturmführer* Werner Jothann, became head of the Construction Inspectorate of the Waffen-SS and Police "Silesia" (*Leiter Bauinspektion der Waffen-SS und Polizei "Schlesien"*).

"Construction of a gas-tight treatment room in the former crema. for the garrison physician," 5 percent of which had been completed.[34]

On November 2, 1944, Jothann drew up an "explanatory report for conversion of the old crematorium into an air-raid shelter for the SS sickbay with an operating room in Concentration Camp Auschwitz O/S. *BW* 98M," in which he described the work to be done:[35]

> *"Conversion of the existing and available rooms of the old crematorium into an air-raid shelter for the SS sickbay with an operating room. The existing central walls and some partitions will be reinforced to 38 cm. Any other necessary partitions will be built. An emergency operating room, two gas-locks, two flushing toilets*[36] *and a water faucet in the operating room are to be installed because a water supply line is available and the sewage line can be extended. Heating will be by furnaces."*

Regarding the time schedule, Jothann adds:

> *"On account of its urgency, work has already started and will be completed within three weeks."*

On the same day, Jothann also drew up a cost estimate[37] for a total amount of 4,300 RM, and a location sketch for the air-raid shelter project.[38] The work was completed in the second half of November.

This, my account of 2005, shows that the authors' statement about the "conversion of an existing gas-tight room in the former crematorium I" is unfounded. In fact, it is openly contradicted by Josten's letter of 26 August 1944, which, among the work to be performed, explicitly mentions "Installation of gas-protection doors," which therefore had not existed before in what the authors claim to have been a "gas chamber." In addition, it was also necessary to create "wall openings" not just for the pipes of the heating stoves, but also for "aeration and ventilation." From this it can be deduced that the four phantom openings in the room's ceiling said to have been utilized for pouring in Zyklon B did not exist back then either, because had they existed, they would have been used for this purpose, and new holes would have been unnecessary.

The authors' fallacious interpretation is therefore just another foolish attempt to corroborate with a real document a fictional story.

II. Section "Provisional Gas Chamber Bunkers I and II in Birkenau"

[8] Document 8 (p. 65)

This is a report on work carried out at the PoW camp (*K.G.L.*), that is, Birkenau,[39] by the company Schlesische Industriebau Lenz & Co. Aktiengesellschaft, dated from 8 July 1942, which exists in two versions: a printed form filled in by hand, and a completely handwritten sheet. The authors observe in this regard:

> *"Among the items listed in the document is an entry about 'the installation of doors at the second gas chamber' (*Türen in 2 Gaskammer*).*
> *The work involved the adaptation as a gas chamber of one of the houses remaining from the former village of Brzezinka (the so-called bunker II 'The Little White House')."* (p. 64)

Here they commit a major blunder, provided it isn't a devious sleight of hand. The proper transcript of the text reads in fact:

> *"1 Pg + 2 M*[aurer] *Einmauern der Tür in d.*[er] *Gaskammer"*
> *"1 Pg*[40] *+ 2 M*[asons] *blocking in of the door in the gas chamber."*

The authors therefore turned the expression "in the" into "in 2", and then they turned the number into the ordinal "second" (Polish *drugiej*, which can be abbreviated as "d."). They inferred from this that the work was done in the "second" bunker, or "Bunker II"!

The fact that the word "*Tür*" is singular deals a serious blow to the authors' fatuous interpretation. In a 1994 paper Franciszek Piper presented a plan of "*Bunker* 2":[41] a house measuring 8.34 m × 17.07 m containing four "gas chambers" sporting a total of four entry doors and the same number of exit doors, so that eight gas-tight doors would have been needed. But this document speaks only of one door to the gas chamber. How can this be reconciled with the alleged "Bunker 2"?

---

39 *Kriegsgefangenenlager*, the official term for the Birkenau camp. The most commonly used abbreviation was KGL. The Auschwitz Main Camp was called *Konzentrationslager* (KL; concentration camp).

40 The printed form lists ten types of workers, including mason (*Maurer*) mentioned in the passage under discussion; among the other nine, the only one starting with the letter "P" is "Polier" (construction foreman); "Pg" could mean "Poliergeselle" (*Geselle* = skilled craftsman without formal foreman degree = *Meistertitel*); this is by analogy with the names of "*Maurergesellen*" and "*Zimmergesellen*" (masons and carpenters) appearing on a *Tagelohnzettel* (day-wage sheet) of Josef Kluge related to construction contracts in Crematorium IV in February 1943. RGVA, 502-2-54, p. 71ff.

41 Piper 1994, p. 162. In Polish literature, beginning with D. Czech's *Auschwitz Chronicle*, and specifically in the study by F. Piper just cited, the two "bunkers" are always numbered with the Arabic numerals 1 and 2. In the book under review, however, they are numbered using the Roman numerals I and II. I explain the reason for this in my comment on Document 20.

This document mentions a "gas chamber" in the "prisoner-of-war camp" at Birkenau, indeed, but it is also true that the only documented "gas chamber" in this camp at that time appears only as part of a project for a delousing facility (*Entlasungsanlage*), first drawn on Map No. 801 of 8 November 1941 (Pressac 1989, p. 55), but also on successive maps (*ibid.*, pp. 56f.). It is well known that in 1942 two mirror-symmetrical disinfestation facilities were being constructed at Birkenau. They bore the identifiers *BW* 5a and 5b (*BW* = *Bauwerk* = structure) and were called "delousing barracks" 1 and 2 in the documents ("*Entlausungsbaracke*"). The disinfestation facility *BW* 5b was completed on 15 July 1942.[42] On June 9 the Central Construction Office commissioned the inmate joinery (*Tischlerei*) to manufacture, among other things, "4 gas-tight double doors 1.60 x 2.00" (*4 Gasdichte Doppeltüren 1,60/2,00*) which were indubitably meant to be used for the delousing gas chamber (*Gaskammer*, two doors) and for the adjoining airlock (*Schleuse*, two doors). Work for that project started on 11 June and was finished on 28 June.[43] For this reason, the installation of one of the two doors in the gas chamber on 8 July is fully compatible with these documents.

The only problem is that the document in question mentions the installation of just one of the two doors. It is, however, far more likely that it refers to *BW* 5a than to the mysterious "Bunker 2," whose existence is not supported by any document. Not to mention that the date of the document contrasts sharply with the date at which "Bunker 2" is said to have been put into operation: 30 June 1942 according to Danuta Czech in her *Auschwitz Chronicle* (Czech 1990, p. 189). The authors are therefore forced to move this date to a time after 8 July.

In another study, Setkiewicz has adduced a documentary "proof" which he was careful not to repeat here. I will give the reason for this shortly. Setkiewicz wrote (2011a, p. 14):

> *"The several documents attesting to the existence in Birkenau of not one but two 'gassing rooms' ('Vergasungsräumen des K.G.L.' in orders from August 6, 1942) date from not earlier than August and September 1942."*

He does not provide any reference, evidently in order to make it difficult to verify the source. This is actually another fatuous trick. It is in fact known that the "Explanatory Report on the preliminary draft for the new construction of the prisoners-of-war camp of the *Waffen*-SS, Auschwitz, Upper Silesia" of 30 October 1941 uses the term "gassing room" ("*Vergasungsraum*") for the delousing chamber of the "delousing barrack"[44] – in the singular, although two such buildings were provided for the PoW camp, referred to as "*BW* 5a de-

---

42 *Baufristenplan* of July 1942 for the PoW camp. RGVA, 502-1-22, p. 31.

43 *Arbeitskarte. Auftrag Nr. 1577* of 9 June 1942. RGVA, 502-1-328, p. 173.

44 *Erläuterungsbericht zum Vorentwurf für den Neubau des Kriegsgefangenenlagers der Waffen-SS, Auschwitz O/S.* RGVA, 502-1-233, p. 16 (p. 4 of the report).

lousing barrack 1" and "*BW* 5b delousing barrack 2."[45] It is therefore indeed obvious that two "gassing rooms" existed in the PoW camp. Since the document mentioned by Setkiewicz undoubtedly refers to these facilities, reproducing it in the book reviewed here would have undermined the authors' agenda, hence he forsook this (pseudo) evidentiary pearl.

[9] Document 9 (p. 69)

This is a list of inmates assigned to construction work at the Birkenau Camp on 17 August 1942. Among the various entries is also this one: "Assigned from the camp – on 7:30 hrs. for special unit 475 inmates, 25 foremen." The authors comment on this as follows (p. 68):

> *"Assigning such a large number of prisoners to work for the Sonderkommando was connected with the preparation of new burning pits in proximity to the extermination sites, mainly bunker I. At the same time, the exhumation of bodies from the mass graves and attempts to burn them on pyres were underway. This fact finds confirmation in accounts by the prisoners Arnost Rosin and Andre Balbin, who were employed at this task."*

This interpretation is based on the pious fiction, tacitly or expressly accepted by all historians of the Auschwitz Museum, that only one single kind of "*Sonderkommando*" existed at Auschwitz, that is, the one working at the crematoria and the "Bunkers." I summarize here what I explained about this in another study (2001, pp. 138-141; 2004b, pp. 101-103), with the necessary additions and corrections.

Danuta Czech explains the origin and meaning of the term "*Sonderkommando*" (special unit) as follows (Czech 1994, p. 371):

> *"The extermination camp created also one other group of people, those who were forced to work in the crematoria and gas chambers – the unfortunate people were assigned to the work of the special unit. The SS used code words if they spoke about the mass extermination of those 'unworthy of life.' It called the mass extermination as well as the transports leading to selection 'special treatment' (often abbreviated as SB). Thus, also, the expression 'special unit.'"*

In other words, since criminal activity described by the code word "special treatment" was allegedly being conducted in the crematoria, the staff employed there had of necessity to be a "special unit." Naturally it was the only work unit at Auschwitz that merited the prefix "special" – otherwise the word would have lost the criminal significance that it possessed according to orthodox Holocaust historiography.

Based on the documents, the reality is entirely different.

---

[45] *Ibid.*, p. 14 (p. 2 of the report).

First of all, in relation to the crematoria, the term "*Sonderkommando*" appears in merely one single document (see my comments on Document 31). In the 5-volume work on the general history of the Auschwitz Camp written by the Museum's historians, Franciszek Piper claims to demonstrate on the basis of two documents that the term in question was referring to the crematoria personnel (Piper 1999, note 360, p. 213). These documents are not mentioned in the book under review: the "Duty roster for Tuesday, 18 July 1944" (dated 17 July),[46] and Headquarters Order No. 8/43 of 20 April 1943.[47] The first of these two documents in fact refers to four names listed on the right: "Buch, Kelm, Schultz, Bickel."[48] Based on the document in question, Piper considers them all "SS members directly employed at the gas chambers and crematoria" (Piper 1999, p. 261). He furthermore states that Buch, Kelm and Schulz are also mentioned as SS supervisors of the crematoria *Sonderkommando* by the witnesses Alter Feinsilber (alias Stanisław Jankowski) and Henryk Tauber (*ibid.*, pp. 261-263), although the first merely speaks of a "*Scharführer* Buch" and a certain "Kell" (Bezwińska *et al.* 1996, p. 45), while the other mentions a certain "Schultz" and "Köln."[49]

A *Scharführer* Buch, an *Unterscharführer* Kelm and an *Unterscharführer* Schultz appear without first names on an undated list containing a column of signatures acknowledging "receipt," so this is probably a payroll list. The list does not give any indication what these individuals were paid for, *i.e.*, what their range of duty was.[50] Heinz Schulz, who according to Piper (whose source spells it "Schul*t*z") was *Kommandoführer* (detail leader) of the crematoria personnel, was identified during the Frankfurt Auschwitz trial as a certain Heinz Arthur Schulz, *Unterscharführer*, who was "leader of the labor detail for dismantlement works" (Fritz Bauer Institut *et al.* 2005, pp. 33519, 46036, 46043). Hermann Buch, who Piper claims to have been a *Kommandoführer* at the crematoria as well, was something entirely different according to the same work in which Piper makes that claim: Buch was actually "head of camp section BIIe," the so-called "family camp for gypsies," from its inception until April 1944. In the biographical note about him comprising eight lines, there is not a hint of his ever having occupied the position of a *Kommandoführer* at the crematoria, which is so important to orthodox historiography (Lasik 1999, p. 239).

[47] "Kommandanturbefehl Nr. 8/43" of 20 April 1943. APMO, D-AuI-4/20. Transcript of this document: Frei *et al.* 2000, pp. 249-254; the term is on p. 251.

[48] In the first edition of my study on *Special Treatment in Auschwitz* I had erroneously linked the term *Sonderkommando* to "Torkontrolle" (2004b, p. 101).

[49] Höss Trial, vol. 11, p. 142.

[50] GARF, 7021-108-54, pp. 97f.

Another similar document exists, the "Duty roster for Thursday, 5 October 1944" from 4 October.[51] The term "*Sonderkommando*" appears on it as well, but only with one name: "Buch." In the second column of that same line we find the words "[river] Sola, Hütte" and next "Kelm."[52]

Since the personnel for the crematoria at that time was divided into eight *Kommandos*, 2 for each crematorium (one day and one night shift),[53] this required 8 *Kommandoführer* for every day. But the first document mentions only four SS noncoms, while the second has only one, so that the "*Sonderkommando*" which that person had to supervise cannot have had anything to do with the crematoria personnel.

In addition, Piper's second document, the Headquarters Order of 20 April 1943, speaks simply of the "pursuit of two Jews who were on the run from the special unit." Therefore, starting from the assumption that only *one single* "special unit" existed at Auschwitz consisting of the crematoria staff, the fact that this term appears in these two document is said to prove that the crematoria personnel was called "special unit"! A classic example of circular reasoning!

However, in documents explicitly mentioning the crematorium staff, its designation is simply "staff of crematorium,"[54] or it is identified by number – "206-B boiler, Crematorium I and II, 207-B boiler, Crematorium II and IV."[55]

There existed moreover numerous other "special units" at Auschwitz, not a single one of which had anything whatsoever to do with the crematoria. For instance (see Mattogno 2004b, pp. 102f.):

– *Sonderkommando Schädlingsbekämpfung*: pest control unit made up of women.
– *Sonderkommando Reinhardt*: women's unit assigned to the sorting of clothing.
– *Sonderkommando Zeppelin*: external unit based in Breslau.
– *Bauhof-Sonderkommando* (*S.K.*): unit working at the storage facility for construction materials.[56]
– *Dwory-Sonderkommando* (*S.K.*): unit working in Dwory – a village about 10 km east of the town of Auschwitz.
– *Buna-Sonderkommando* (*S.K.*): unit working in Monowitz.
– *Bekleidungs-Werkstätte-Sonderkommando* (Bekl.Werkst.S.K.): unit in the clothing workshops producing clothing.
– *Sonderkommando Sola-Hütte*.

[56] *Ibid.*, p. 149.

Other *Sonderkommandos* appearing in documents adduced by the authors will be dealt with further below.

Turning back to Document 9, it is a simply an utterly unfounded conjecture that the "*Sonderkommando*" mentioned in the list of 17 August 1942 had anything to do with any personnel working at the phantasmagorical "bunker." The orthodox "information" about that alleged "*Sonderkommando*" stems exclusively from testimonies which are very contradictory to boot. Eric Friedler *et al.* (2005, p. 77) wrote in this regard:

> *"The labor detail consisting of up to 50 inmates per bunker which was deployed directly at the gas chambers was called* Sonderkommando *right from the start. There existed another detail with Jewish workers between May and September, however, which was deployed by the SS for the removal of traces of the mass murder. The task of this 'burial detail' was to excavate the deep pits in which the corpses of the gassed victims from Bunkers 1 and 2 had been buried. Finally, in September 1942 the burial detail and the* Sonderkommando *were merged by the SS, and from then on it was called merely* Sonderkommando.*"*

If viewed that way, the term used in the list of 17 August does not refer to a burial unit, as the authors affirm (which at that time, if we follow Friedler *et al.*, wasn't called "*Sonderkommando*" but "*Begrabungskommando*"), but would have been a "gassing unit."

In her entry for 4 July 1942, Czech writes in her *Auschwitz Chronicle* about the origins of the "*Sonderkommando*" (1990, p. 192):

> *"The so-called Sonderkommando (Special Squad) is formed, consisting of several dozen Jewish prisoners. They must dig pits near the bunker and bury those who are killed in the gas chambers. The squad is housed in the barracks in the men's camp in Birkenau. It is completely isolated from the other prisoners."*

The source is a report of the Polish resistance. The date, however, is Czech's invention. In fact, the "Memorandum on the State of the Nation for the Period 16 July to 25 August 1942" conveyed the following (Marczewska/Ważniewski 1968, p. 37):

> *"A few dozen, physically very strong detainees are selected from each group of new arrivals. This is the special company* [*kompania specjalna*] *which at night digs graves and buries the slain. This company – strictly isolated – was later exterminated in the gas chamber; a new one replaced it."*

The Polish underground periodical *Informacja Bieżąca* (*Current Information*) published in its no. 31 of 26 September 1942 a "Report from Auschwitz" which contains the same claims with slight variations (*ibid.*, p. 39):

> *"100 physically very strong people are selected from the group of new arrivals. This is the special company* [*kompania specjalna*] *which at night digs graves and buries the slain. A short while later, this strictly isolated company was exterminated in the gas chamber; a new one replaced it."*

Arnošt Rosin, whom the authors call as their witness, stated that two weeks after his arrival at Auschwitz – which occurred on 17 April 1942, hence in late April/early May – 200 detainees of his transport were selected and isolated in a hut. The next day 50 detainees were taken away. They were all assigned to the *Sonderkommando*. The group of 150 inmates to which Rosin belonged was led into the birch wood near Birkenau. They had to excavate mass graves near the "white farmhouse," *i.e.* "Bunker 2" – although according to the orthodox version of events, this structure did not yet exist at that time. The other 50 detainees were allegedly involved in the gassing of the victims and the removal of their corpses (Friedler *et al.* 2005, pp. 78f.).

It is unclear how these claims can be reconciled: were there a few dozen, 100 or 200 prisoners in the *Sonderkommando*? Czech writes even that *300* prisoners of the *Sonderkommando* who had been employed in the exhumation and cremation of 107,000 corpses were killed in the "gas chamber" of Crematorium I at Auschwitz on 3 December 1942 (1990, pp. 277f.). This number is taken from a deposition Arnošt Rosin made during the 16th session of the trial of the Auschwitz camp garrison. The witness stated:[57]

> *"On 3 December 1942, the* Sonderkommando*, numbering 300 people, was gassed at Auschwitz during the preparation of an escape. The rest of the* Sonderkommando*, numbering 10-12 people, remained in the block and were subsequently led into the so-called 'death chamber' – this was the place for the corpses – and the defendant Plagge himself shot them."*

To top it off, the witness Stanisław Jankowski, also adduced by Czech, asserted instead that the *Sonderkommando* had *390* inmates and was "gassed" in November or December 1942 (Bezwińska *et al.* 1996, p. 48). So how many? A few dozen? 100? 200? 300? 390? No, the authors of the reviewed book say: 500!

Leaving aside these numerical contradictions and those relating to the extermination of the *Sonderkommando*, which according to the Polish resistance's Memorandum must have occurred already before 25 August 1942 (if at all) but which is completely ignored by Czech, the authors should address how the numerical data quoted here can be reconciled with the document under discussion. If the maximum number of prisoners in the *Sonderkommando* was 390, how do they explain the assignment to it of 500 inmates on 17 August 1942?

---

[57] Trial of the Auschwitz camp garrison, vol. VII, p. 7.

The authors also misinterpret the meaning of the document: "Assigned from the camp – on 7:30 hrs. for special unit 475 inmates, 25 foremen" does not mean that the *Sonderkommando* had been permanently increased to 475 inmates and 25 foremen, but that these detainees had been made available only for that particular day at 7:30 hrs. The comparison between the two pages of the document shows that the total number of prisoners employed remained unchanged (3,000) and that the 475 inmates transferred to the *Sonderkommando* consisted mainly of "*Planierungsarbeiter*" (workers engaged in leveling the ground), whose tally went down from 2,145 on August 16 to 1,710 on August 17. Some inmate workers also came from the pool originally assigned to leveling the ground for the future SS lodgings ("*Pl. Unterkunft-SS*"), which decreased from 195 to 95. It is important to point out here that the 3,000 workers in question were chosen based on their profession, as is reflected in a parallel document with the headline "Inmate deployment of 27 February 1942."[58] The two documents published by the authors were part of a handwritten list which was certainly meant for internal use only, while the one I mentioned was a typewritten official document which reported the pertinent data in more detail.

As mentioned above, the alleged first *Sonderkommando* was formed toward late April/early May 1942 according to Rosin, or on 4 July if we follow Czech. Leaving aside this chronological contradiction, both declare that its inmates were Jews taken directly from a transport, without first passing through the official labor deployment procedure. But the 475 inmates and 25 foremen in question were rather precisely part of this official labor pool, and they remained part of it even after their temporary assignment to the *Sonderkommando*, not to mention that there is no evidence that they were Jews.

In addition, it is unknown which *Sonderkommando* the document in question relates to, and nothing in it indicates that it was involved in the excavation of mass graves or that it had any relationship to the elusive "bunkers."

The authors' interpretation is moreover in striking contrast to one of the cornerstones of their version of the origin of outdoor cremations. In her *Auschwitz Chronicle* under the date of 16 September 1942, Czech (1990, p. 238f.) mentions the fact that Camp Commander Rudolf Höss, accompanied by SS-*Untersturmführer* Franz Hössler and SS-*Untersturmführer* Walter Dejaco, visit SS-*Standartenführer* Paul Blobel on that date, supposedly in Chełmno, to learn about, and adopt for Auschwitz, the procedures and cremation devices employed in that camp (see Mattogno 2008). This means that prior to that date Höss would have been ignorant as to how to cremate corpses buried at Auschwitz (otherwise he wouldn't have turned to Blobel to find out about it), so he could not possibly have ordered the preparation of "new burning pits" on August 17.

---

[58] RGVA, 502-1-67, pp. 94f. See DOCUMENT 3.

Here is another problem. Historians at the Auschwitz Museum claim that the corpses of the victims of the "bunkers" of Birkenau were not burned in cremation pits before Heinrich Himmler's visit to Auschwitz on 17 and 18 July 1942. In this regard Czech explicitly states (1990, p. 199):

> *"At this time, the corpses* [of Bunker 2] *are not yet being burned but are piled up in pits and buried."*

Himmler allegedly decided to have the bodies cremated rather than buried, and "shortly after Himmler's visit" Blobel is said to have showed up at Auschwitz "with orders to exhume all buried bodies, burn them, and to scatter the ashes to prevent the possible reconstruction of the number of victims" (Piper 1994, p. 163), although no paper trail exists of Blobel's alleged visit to Auschwitz, and it is not even mentioned in Czech's *Auschwitz Chronicle*.

Hence, if we follow the orthodox Holocaust logic, then the order to exhume and cremate the buried victims is said to have arrive at Auschwitz already in July 1942 ("shortly after" Himmler's visit), but, inexplicably, Höss went to see Blobel for advice on cremating exhumed corpses only almost two months later! Meanwhile, according to the authors, he would have ordered the excavation of "new burning pits," which indicates that, in their opinion, at that time there were already "old" cremation pits, *i.e.* that outdoor cremations were already happening.

When open-air mass cremations began on 21 September after Höss's return to Auschwitz, the procedures adopted are said to have been rather primitive; after attempts were allegedly made to cremate the corpses on pyres, they were eventually simply burned directly in the pits (*ibid*., pp. 305f.). Since Höss's travel permit concerned the visit to an "experimental station for field furnaces Operation Reinhard,"[59] which were masonry furnaces requiring "building materials,"[60] it is unclear why Höss would instead apply the crude methods of pyres and burning pits at Auschwitz.

In my comments on Document 13 I will examine Setkiewicz's pathetic attempt to unravel somewhat this web of contradictions.

In conclusion, it is unknown to which *Sonderkommando* the document in question refers, and nothing indicates that it was involved in the excavation of mass graves or had any relationship with the elusive "bunkers." Hence Document 9 basically does not prove anything. Just like all the other documents they mentioned later on, it is of value to the authors only due to the myth of the *Sonderkommando*, the sterile vicious circle which assumes apodictically that merely one *Sonderkommando* existed at Auschwitz, and that it was of necessity devoted to cremation and gassings. Then these scholars triumphantly brandish documents that mention the term in question (and others with the

---

[59] *Fahrgenehmigung* of 15 September 1942. AGK, NTN, 94, p. 170. Reproduced in Mattogno 2008, p. 85.

[60] *Ibid*., p. 84, *Reisebericht über die Dienstfahrt nach Litzmannstadt*. RGVA, 502-1-336, p. 69.

"*Sonder*-" prefix) as "proof" of the claimed reality of the alleged homicidal gassings.

[10] Document 10 (pp. 71f.)

This is the well-known "*Aktenvermerk*" (file memo) by *SS-Untersturmführer* Fritz Ertl of 21 August 1942[61] mentioning "bathing facilities for special operations," which the authors, following the common practice of the Holocaust orthodoxy, claim to be the elusive "bunkers":

> *"Protocol of a discussion that took place at KL Auschwitz on August 19, 1942. Representatives of the camp and the Zentralbauleitung negotiated with the engineer Kurt Prüfer, a specialist from the Topf und Söhne company from Erfurt, whose products included furnaces for cremating corpses. This conference was probably an outcome of Himmler's July 1942 orders calling for an expansion of the capacity for exterminating Jews at KL Auschwitz. Instead of being buried in mass graves, the bodies of the people murdered in the gas chambers were henceforth to be burned. During the discussion it was decided to build a second crematorium based on the system of five three-retort furnaces (the future crematorium III) and the installing of crematorium furnaces next to bunkers I and II. They are defined in this document as 'bathhouses for special operations' (*Badeanstalten für Sonderaktionen*). The decision to build new furnaces adjacent to the bunkers was revised several weeks later, and it was determined that the equipment for burning corpses would be placed in newly designed facilities (later crematoria IV and V)."* (p. 70)

This absolutely untenable claim has already been abundantly refuted by me in two other studies (2004b, pp. 66-71; 2019, pp. 186-190). Here I will merely summarize the three key points of my arguments. First I quote the crucial passage of this document:[62]

> *"Regarding the installation of 2 three-muffle furnaces each at the 'bathing facilities for special operations' it was proposed by engineer Prüfer that the furnaces be diverted from an already completed shipment to Mogilev* [in White Russia]*, and the administrative director, who was at the SS Main Office of Economic Administration in Berlin, was immediately informed of this by telephone and asked to make further arrangements."*

First of all, the text does not explicitly state that there were two such bathing facilities. If it was planned to install two furnaces at each of these "bathing facilities," the two three-muffle furnaces originally ordered for the PoW camp would have sufficed for only one "bathing facility," but no document mentions a further order for three-muffle furnaces .

---

61 RGVA, 502-1-313, p. 159.

62 RGVA, 502-1-313, p. 159; see Mattogno/Deana 2015, vol. 1, p. 233, for the full text and context.

Next, in August 1942 no structure existed bearing the name "bathing facilities for special operations" or any similar term. None of the buildings already erected or under construction had anything whatsoever to do with "bathing facilities." And this, even though for this month we know exactly all the structures that existed at Birkenau; we know when they were ordered, when their construction began, what their number and their name was, what their extent of completion was, and where they were located. This information is contained in the "Construction schedule 1942. Month reported: August"[63] and the plan of Birkenau dated 15 August 1942 (Pressac 1989, p. 209). These documents obviously do not mention the phantasmagorical "bunkers" of Birkenau either.

These "bathing facilities" don't show up in any project of the Auschwitz-Birkenau Camp, in any construction report, in any plan or map, which demonstrates that these facilities were only in a planning stage at best. This is additional proof that they could have had nothing to do with "Bunkers" 1 and 2, which were supposedly already in operation in August of 1942.

My third point is that no document shows that the "special operations" were homicidal gassing events. As I have shown in my specific study, these operations referred to the treatment of Jewish transports in general (*Sondertransporte* = special transports) with all related operations, like registration, disinfestation and admission of deportees (2004b, pp. 60-87).

Finally, while there are "concordant" documents mentioning "bathing facilities" and crematoria in the context of sanitation and health care (2019, pp. 136-140), there is not a single document mentioning them in a criminal context. I will elaborate on the actual objects which these "bathing facilities" most likely refer to when commenting on the authors' "Introduction."

[11] Document 11 (p. 75)

The authors present it as follows:

> *"Work card for the electricians' Kommando from August 22, 1942, concerning the installation for the Sonderkommando of an aboveground power line 200 m in length and a power wire 600 m in length to 19 burning sites (*19 Brennstellen*). The document refers to the beginning of the burning of corpses retrieved from the mass graves. The power line was associated with the necessity of illuminating the area where the burning of corpses went on all day, and also at night."* (p. 74)

The English text translates the German term "*Brennstellen*" as "burning sites", while the Polish text uses the words "*miejsc spaleniskowych*", which is cremation sites (since "*spalenie*" means cremation when dealing with corpses).

---

63 RGVA, 502-1-22, pp. 40f.

Here the authors commit a major translation blunder. "*Brennstelle*" is in fact a German technical term referring in general to a point for connecting lighting fixtures or other electrical loads (electrical outlet).

This document is so "new" that I mentioned it already in 2001 (p. 140; Engl.: 2004b, p. 102, fn. 358). The archival reference is RGVA, 502-1-316, p. 34. This is a work report (*Arbeitskarte*) of the inmate electrician detail (*Elektriker-Kommando*) for Order No. 1888 of 22 August 1942 regarding the construction site of structure no. 20 at Birkenau. The text states:

> *"For installing of the special unit Birkenau BW 20 PoW camp, the following work is to be carried out: installation and supply line for the special unit consisting of: 19 lighting outlets, 1 supply line 200 m overhead line and 600 m wire 4 x 10."*

The work started on 20 August and was done on the 22nd, requiring 60 specialist man-hours and 60 unskilled man-hours.

The authors do not show the reverse of the document, which states: "The material was obtained directly from the construction office" followed by the number of inmate labor hours used and the total costs of 6 RM.[64] An assignment sheet no. 1888 also exists from the same date and addressed to the "inmate electricians." It contains the same text as the work report.[65]

It is unclear which *Sonderkommando* the two documents refer to, and the way they are phrased does not help to elucidate it either: it speaks of installation "of the" and "for the" *Sonderkommando*.

Fact is that the document refers to *BW* 20 of the PoW Camp, which was the *Kraftstromanlage*, the high-voltage power system, hence the *Sonderkommando* mentioned in the document was not linked to the legendary "bunkers."

The authors' interpretation is intentionally misleading, because the document clearly says that "19 lighting outlets" were part of the work the electricians had to carry out, not the places where they had to work, so here the authors are committing an unambiguous fraud.

One last observation. The authors state that the "power line was associated with the necessity of illuminating the area where the burning of corpses went on all day, and also at night." Such a conclusion is unfounded, because the document does not mention at all any floodlights necessary for illumination. If and when such an illumination was requested, the respective "work report" stated this clearly, as for example in the case of Crematorium II. On 20 November 1942, the Central Construction Office drafted a "work report" for Order No. 98/291 which stated:[66]

---

64 RGVA, 502-1-316, p. 34a.
65 RGVA, 502-1-316, p. 33. See DOCUMENT 4.
66 RGVA, 502-2-8, pp. 1-1a. See DOCUMENT 5.

> *"Concerning: Crematorium II – BW No. 30 in PoW camp the following work has to be carried out: construction illumination in Crematorium II, as well as adjusting the floodlights for night shift // guard detail."*

The document's reverse lists the required material, including electric wire (*Leitung*), floodlights (*Scheinwerfer*) and incandescent bulbs (*Glühlampe*).

[12] Document 12 (p. 77)

This is page 113 of an inmate-labor-deployment register. The authors declare:

> *"Entry no. 1131 of August 22, 1942 mentions the receipt of a request to assign 50 additional prisoners to the Sonderkommando (*Verstärkung des Sonderkdo. um 50 Häftlingen [sic]*). This is further confirmation of the expansion of the tasks envisioned for this labor detail in the third week of August 1942, when the recovery of bodies from the mass graves and the burning on pyres began."* (p. 76)

This interpretation is also utterly unfounded. The document is subdivided into eight columns, only seven of which are filled in:

1) "*Lfd. Nr.*," serial number: 1131

2) "*Eingangs-Datum*," date of receipt: 20 August 1942

3) "*Aktenzeichen*," file reference (*ohne*)

4) "*von wem*," from whom: administration of inmate property (*Gefangenen-Eigentumsverwaltung*)

5) "*Inhalt*," contents: "reinforcement of special unit by 50 inmates" (*Verstärkung des Sonderkommandos um 50 Häftlinge*)

6) "*Sachbearbeiter*," responsible clerk: Klapper

7) "*Weitergeleitet an*," forwarded to: "labor service" (*Arbeitsdienst*).

Clearly, then, on 20 August 1942 the administration of inmate property requested the augmentation of its special unit by 50 inmates, all this in keeping with the normal practice of the camp's labor service. That is, these 50 inmates were part of the camp's normal labor pool, so that the same considerations apply here as I have explained in relation to Document 9. The inmates' property, which had been seized by the camp administration on the inmates' arrival, were called "*Effekten*" (personal effects). Their sorting and cleaning, as I will show with my comments to Document 31, was carried out by a dedicated *Sonderkommando*, which in fact consisted of 50 detainees. It has nothing to do with any sinister activities.

[13] Document 13 (p. 79)

This is travel order (*Fahrbefehl*) no. 7 of 7 September 1942 for a five-ton truck. The authors stated about it:

> *"The purpose of the trip is listed as the delivery of wood from Radostowice. In that locality, as well as in Międzyrzecze (Messersitz), Stara Wieś*

> *(Altdorf), and Kobiór (Kobier) on the grounds of the Pszczyna forestry office (Oberforstamt Pless), there were prisoner Kommandos (small subcamps would later be established there) tasked with gathering branches and scrap wood used for burning corpses in Birkenau."* (p. 78)

The only information which the Auschwitz Museum has on Radostowice (in German Radostowitz) originates from statements of a former detainee who worked there between late 1941 and January-February 1943. Piotr Setkiewicz reported the essentials. According to this, the detainees in that labor detail were of all nationalities, but mostly Jews. They worked from 7 am to 5 pm. The work consisting of clearing out young deciduous trees was carried out along four lines of woodland, each 750 meters long, called G, H, J and K. They cut down especially deciduous trees, like oaks and birches, because these allegedly burned better when green. At the end of the work day, trucks came in the evening which loaded up the freshly cut wood and brought it to Birkenau (Setkiewicz 2010, pp. 147f.).

At the beginning of his article, Setkiewicz tries to put the document in question in the historical context of the alleged origins of open-air cremations at Auschwitz. After referring to the cremation order allegedly issued by Himmler during his visit to Auschwitz on 17 and 18 July 1942, he writes (*ibid.*, pp. 140f.):

> *"News of the intention to cremate corpses from mass graves in Birkenau reached Kurt Prüfer early, the engineer of Topf & Söhne company, because on 21 August 1942 he proposed to use for this purpose two field cremation furnaces. His proposal was rejected very quickly by the SS, however, who opted instead for the cheaper and safer solution as used at the extermination camp at Chełmno upon Ner – the cremation of corpses on pyres. Höss put the Rapportführer of the Auschwitz camp, SS-Untersturmführer Franz Hössler, in charge of carrying out that task.*
>
> *The cremation of corpses in pits or on pyres began at Birkenau probably around the turn of August to September, initially using firewood stock (wood waste), but later, around 7-8 September, also systematically by beginning to bring in wood from outside. This results from the analysis of data on truck departures sent from the camp to places that are located within the large forest areas in Tychy, Żory and Pszczyna.*
>
> *Trucks with 5 tons of payload headed to Radostowice at Pszczyna on 7, 8 and 9 September. The purpose given for the trip was: 'Abholung von Holz, Holztransport' (pick up wood, transport of wood).*
>
> *We need to understand that at that time no one at the SS camp garrison initially had any experience in the construction of cremation pyres, and not even written instructions existed about it. For this reason, problems arose regarding the cremation of corpses during the initial period of open-air cremations in Birkenau: either the cremations lasted too long, or the con-*

> *sumption of wood was too high. Höss therefore had to recognize that the difficulties were so serious that in mid-September he decided to stop the operation and to make a trip to the extermination center at Chełmno upon Ner in order to inquire about the corpse cremation methods used there."*

This is an entirely fictitious historical reconstruction, invented in order to try to iron out the insuperable timing disparities arising from the previous orthodox version of the genesis of open-air cremations at Auschwitz.

Setkiewicz infers the start date of these cremations from a "letter from the Auschwitz Camp" dated 29 August 1942, which relates this fanciful story (Marczewska/Ważniewski 1968, p. 43):

> *"Most terrible are the mass executions in gas chambers especially designed for this purpose. There are two of them, and they can hold 1,200 people. In them, bathrooms with showers are installed, from which, alas, gas flows instead of water. In this way especially entire transports of people are killed who are left clueless. They are told that they will take a bath, they are even given towels – already 300,000 people have perished this way. Once they were buried in mass graves; now they* [the bodies] *are burned outdoors in specially dug pits* [*Kiedyś zakopywano w rowach, dziś palą na wolnym powietrzu, w rowach specjalnie wykopanych*]. *Death occurs by suffocation, because blood streamed from nose and mouth."*

Hence, if the first documented transport of firewood from outside the camp arrived at Auschwitz on September 7 – ponders Setkiewicz – then wood stored inside the camp must have been used prior to that. This is merely a conjecture, because nothing in the above-quoted letter confirms the accuracy of this allegation.

The alleged difficulties encountered during the initial stage of outdoor cremation are only a puerile trick, devoid even of anecdotal support, in order to account for Höss's visit to the field furnaces (*Feldöfen*) of Operation Reinhardt on 16 September 1942. But here the contradiction persists, because Setkiewicz does not explain why the commandant of Auschwitz, after inspecting these field furnaces, returned to Auschwitz yet kept the cremation system in place (on the surface or in pits) which, according to the Polish historian, had presented such difficulties that they induced Höss to inspect these furnaces in the first place. As I mentioned above, the travel permission of 15 September 1942 authorizing Höss's trip explicitly states:[67]

> *"Travel permit for passenger car from Au. to Litzmannstadt* [Łódź] *and back for inspecting the experimental station for field furnaces Operation Reinhard is granted herewith for 16 Sept.* [19]*42."*

If we consider the reference in SS-*Untersturmführer* Ertl's file memo of 21 August 1942 to Prüfer's presence at Auschwitz on 19 and 20 August and to

---

[67] AGK, NTN, 94, p. 170. Reproduced in Mattogno 2008, p. 85.

his proposal for the crematoria, Setkiewicz's reconstruction appears grotesque: Despite having at his disposal one of the best German cremation specialists – *i.e.* Prüfer – Höss is said to have struggled to find merely crude and improvised solutions. Then he allegedly sought advice from Blobel, who, when it comes to outdoor cremations, knew just as much about it as Höss.

For the three travel orders mentioned by Setkiewicz, dated 7, 8 and 9 September 1942, he gives as reference "APMA-B. D-AUI-4 / 29-31, Fahrbefehl Volume 1 pp. 671-673" (Setkiewicz 2010, note 5, p. 140). This suggests that the Auschwitz Museum is in possession of at least two volumes of these documents, and that the first one has at least 673 pages. This Polish historian nevertheless mentions only the three above-mentioned documents, which therefore must be the only ones known within the collection of documents for 1942. Since Document 13 speaks of a five-ton truck with trailer (*mit Anhänger*), even if we assume three loads of 10 tons each, the total amount of wood brought to the camp (the document does not specify that the destination was Birkenau) would be 30 tons, enough for the cremation of merely some 100 corpses.[68] Following Höss's statement, Czech states that as of 3 December 1942 107,000 corpses had been cremated outdoors (Czech 1990, p. 277). In this case, (107,000 corpses × 320 kg/corpse =) 34,240 tons of fresh wood would have been required for their cremation, which is the equivalent of 3,424 trips of one five-ton truck with a trailer. This means that the collection of travel orders should contain at least hundreds of travel orders for hauling wood, not just three! I will return to that issue in Chapter 12 of Part Two.

The premise of the authors' (and Setkiewicz's) interpretation of Document 13 is that transporting firewood to Auschwitz served exclusively the cremation of corpses, but this is a naïve and unfounded assumption. We know that the SS men who lived with their families near the camp routinely received supplies of firewood. For example, Garrison Order no. 55/43 of 15 December 1943 mandates the following (Frei *et al.* 2000, p. 381):

> *"Considering the extraordinary difficulties in supplying firewood, it is ordered hereby that the households of SS members get only two loads of wood delivered during the calendar year 1 Jan. 1944 – 31 Dec. 1944. For the month of December there will be no more supplies. Since firewood is allowed to be used only for firing up, and in the Reich 10 families receive 1 cubic meter* [of wood]*, one absolutely has to make do with the allocated quantity, which is very generous anyway."*

[68] Since these are said to have been fresh corpses, I assume a consumption of 2.82 kg dry wood per 1 kg of organic matter, equivalent to 5.36 kg of green wood, and with Robert Jan van Pelt an average weight of the bodies of 60 kg. (See Mattogno/Kues/Graf 2015, vol. II, pp. 1111, 1286f.). This results in a consumption of about 320 kg of fresh wood per corpse, so the 30 tons of green wood would be enough for the cremation of less than 100 corpses.

Nothing, therefore, rules out that the three wood transports mentioned above served for heating family homes.

[14] Document 14 (p. 81)

This is the well-known report "Visit of SS-*Obergruppenführer* Pohl on 23 Sept. 1942" written by the head of the Central Construction Office Bischoff.[69]

Among the various sites visited by Pohl (head of the SS-*WVHA*), there is this: "Station 2 of Aktion Reinhard." In their comments, the authors simply highlight this entry without any explanation. In their Introduction, however, they argue that this "Station 2 of Aktion Reinhard" refers to "Bunker 2," a conjecture already proposed by Bertrand Perz and Thomas Sandkühler. I have already refuted this imaginative interpretation in another study, where I discussed the document in question (2008, pp. 16-21). This document contains another important reference to the "Aktion Reinhard": "disinfestation and storage of personal belongings/Aktion Reinhard." I therefore concluded that this term referred to the so-called "Kanada I," that is structure *BW* 28, which was called "barracks for delousing and personal effects" ("*Entlausungs- und Effektenbaracken*"). This is confirmed by the report on Pohl's visit (see Document 27), which identifies the "disinfestation and storage of personal belongings/Aktion Reinhard" with "delousing chamber and personal effects warehouses (resettlement of Jews)," as I will explain in my comments on Document 27.

The "Station 2 of Aktion Reinhard" was a huge storage facility for inmate belongings. It was called "Station 2" because "Station 1," the main warehouse, was precisely the above-mentioned *BW* 28. This interpretation is confirmed by the fact that even in May-June 1944 in Birkenau there was a "*Sonderkommando* Reinhardt" in which 2,505 inmates worked on 19 June.[70]

[15] Document 15 (p. 83)

This is a "Detail of a March 1943 map showing the expansion of the Birkenau Camp." The authors elaborate:

> *"Bunker II, together with three adjacent wooden barracks, is visible. One of them is crossed out, probably as a result of the updating of the map in 1944, when two barracks used for undressing by the Jews doomed to death in the gas chamber were erected at the same place where three barracks, subsequently dismantled, had stood in 1942."* (p. 82)

The document in question is the "Development Map for the Erection and Extension of the Concentration and POW Camp, Map No. 2215," dated March

---

69 RGVA, 502-1-19, p. 86.

70 "Übersicht über Anzahl und Einsatz der weiblichen Häftlinge des Konzentrationslagers Auschwitz O/S. 19. Juni 1943." GARF, 7021-108-33, p. 153.

1943,[71] a section enlargement of which I published in my study on the "bunkers" of Birkenau (2004a, Doc. 8, p. 205), along with other similar maps which the authors ignore. I reiterate and expand the respective discussion of this issue as laid out in my study (*ibid.*, p. 40).

This master plan shows the complete map of the Birkenau Camp. To the north of Construction Section (*BA=Bauabschnitt*) III, just outside the camp enclosure, the houses 586, 587 and 588 are visible, together with other houses further north (*H*. 581, 582, 583, 584, 585, 589, 590) as well as the group of houses from the former village of Birkenau to the east of *BA* III (DOCUMENT 6). The house that orthodox historiography today calls "Bunker 1" (the one closest to the camp, located further down in DOCUMENT 10 in the Appendix) and the other five houses to the west of it (two of which were located next to the road bifurcation further west), all without ID number, because they had been demolished. The septic tank (*Erdklärbecken*), as is apparent from a comparison of my DOCUMENTS 10 and 16a, was to be built to the south (left) of the vertical road visible in DOCUMENT 10 and barely visible in DOCUMENT 16a, while the group of four buildings (including the alleged "Bunker 1") was north of it (right), so that there was no overlap between the septic tank and the alleged "Bunker 1." Therefore, if the above four buildings do not appear in Plan 2215 of March 1943, then this is precisely because they had been demolished.

To the west of the *Zentralsauna*, however, the house still appears which today is known as "Bunker 2" by orthodox historiography, as well as another house predating the camp in front of it (to which I will return later), both without identification numbers, which had not yet been demolished. Near them on the map, the Soviets have crudely sketched in three rectangles supposed to represent the alleged undressing barracks of "Bunker 2," which, however, should have been only two in number, not three.[72] Realizing their mistake, the Soviets struck out the third barrack with three strokes of the pen! (See DOCUMENT 7.)

That those "barracks" are indeed the work of the Soviets can be seen above all from their drafting technique. In the drawings of barracks done by the Central Construction Office[73] the lines forming the outer edges intersect crosswise at each corner, while those drawn by the Soviets form a closed angle and show, moreover, a thicker pen stroke. Furthermore, there is another version of this drawing, identical except for the fact that the "septic tank" was changed into a "*sewage plant*" (*Kläranlage*). On this map, the two houses mentioned

---

[71] RGVA, 502-2-93, p. 1.

[72] This applies to the first claimed operational phase of "Bunker 2"; in mid-May 1944, when it is said to have resumed activity, three barracks were installed there according to F. Müller (1979, pp. 211f.).

[73] The map was drawn by detainee no. 471, the Polish draftsman Alfred Brzybylski.

above appear to the west of the central sauna, – again without an identification number – but there is no trace of any barracks.[74]

It is true that the Central Construction Office drew its maps in several copies, which were then used for the necessary updates. The upgraded map became in turn an official document, sanctioned by its registration in the issuance ledger, which was confirmed by the stamp "Entered in map issuance ledger." Both maps in question bear this stamp; the one on which the Soviets drew the barracks has the stamp "Entered in map issuance ledger under no. 3373 / 10 Sep 43"; the other has the stamp "Entered in map issuance ledger under no. 9288 / 13 Feb 44" (see DOCUMENTs 7a & 8a). Once recorded in the issuance ledger, changes to the two maps in question, like all the others, were no longer permitted. But since the barracks of the elusive "Bunker 2" were allegedly erected in May 1944, it is clear that, for chronological reasons, neither of these plans could have been updated to show the claimed barracks, so that the authors' explanation is totally inconsistent with the facts.

In this context they committed a serious omission. In the area of "Bunker 2," both maps show *two* pre-existing houses, of which the top one (west) is said to have been "Bunker 2," but for none of the witnesses the second house existed at all. This is also true for all the descriptions of "Bunker 2" given by the key witness Szlama Dragon:[75]

> *"We were led into a forest where there was a brick cottage with a straw-thatched roof. The windows were walled up. The door leading into the house had a metal plate with the inscription 'Hochspannung – Lebensgefahr'* [high-voltage – danger to life]. *At about 30 to 40 meters from this cottage stood two wooden barracks. On the other side of the house there were four trenches, 30 m long, 7 m wide, and 3 m deep."*

There is no reference to a second building. The authors of course know better than to even address the fact that a second building is shown on both maps. Another key element also appears on these two maps which the authors don't address at all. I proffer the necessary explanations which I have given in my study on the "bunkers" of Birkenau.

From 31 March 1942 forward, each site of the construction project Concentration Camp Auschwitz was assigned an identification number preceded by the letters *BW*. All administrative acts related to a *Bauwerk* had to be marked with the reference "*BW 21/7b (Bau) 13*," in which 21/7b identified the

account, "*(Bau) 13*" the title.[76] For the prisoner-of-war camp (the Birkenau Camp), such dispositions had already come into force in February 1942.[77]

During the course of the construction of the Auschwitz-Birkenau Camp, the local population was evacuated;[78] many houses that stood in the way of the plans of the SS were demolished, but countless others located within the "area of interest" of the camp remained intact and were incorporated into the administration of the camp and entrusted to the SS New Construction Office (later to become SS Construction Office and finally SS Central Construction Office). Some, though very few, houses were neither demolished nor incorporated into the camp administration.

The SS New Construction Office carried out a census of the incorporated houses and gave a serial number to each one. Numbering proceeded by zones, and one of the last zones was that of the Auschwitz railroad station. The February 1942 report of the surveying section at SS New Construction Office mentions the following activity:[79]

"Numbering of the houses between Alter and Neuer Bahnhofstrasse."

For example, in the former village of Brzezinka (Birkenau), the SS New Construction Office incorporated some forty houses, to which it assigned the numbers from 600 to 640 (see DOCUMENT 6).

On September 10, 1944, the Central Construction Office renumbered the houses to reflect a renaming of the streets.[80]

All work on the houses was planned and carried out by the above office, which retained responsibility for maintaining them even after the work had been completed and the building had been handed over to the camp administration. For example, in October 1944 the Central Construction Office took on the inspection and repair of the damage caused by the U.S. aerial bombardment of September 13, 1944, creating for this purpose a special *Bauwerk* no. 167.[81] Among the structures destroyed or damaged were 18 buildings[82]

[82] Buildings no. 134, 135, 136, 138, 128, 129, 116, 117, 118, 119, 120, 157A, 157B, 157C, 157E, 157D, 125.

and 63 houses.[83] For each house and each building the Central Construction Office made a damage assessment and a cost estimate for repairs.[84] In the village of Broschkowitz some thirty houses were set aside for those who had been displaced.[85]

Some existing Polish houses were incorporated into the construction project Concentration Camp Auschwitz and were given the number of the corresponding *Bauwerk*. For example, Houses 130, 132, 150, 151, 152 and 171 became part of *BW* 36B (housing for officers and NCOs).[86]

From the administrative point of view, the creation of a *Bauwerk* enabled the accomplishment of a complex series of bureaucratic steps, embodied in the drafting of a number of documents: besides the sketch of the location, the construction specification, and the cost estimate already mentioned, they included a drawing, an explanatory report, a transfer to the camp administration, and a notice of completion. For each *Bauwerk*, it was moreover necessary to keep a cash ledger in which all work done on the *Bauwerk* and the accompanying payments were recorded, and which reflected, so to speak, the administrative life of a *Bauwerk* (see Mattogno 2015, pp. 38 and 45). The construction or the modification was carried out by the Central Construction Office, using either its own detainees or civilian companies called in from the outside. Ordinary jobs were done by the workshops of the Central Construction Office, which had at its disposal a number of *Kommandos* of skilled workmen (blacksmiths, painters, carpenters, bricklayers, plumbers, etc.).

Turning back to the two maps no. 2215 of March 1943, they show north and east of *BA* III fifty houses, each of which is marked with a number preceded by the letter "*H*" (= *Haus*, house). It is precisely these pre-existing houses which had been taken over by the Central Construction Office and which were to be used for a specific purpose (mostly housing for families of married SS officers and NCOs, but House no. 642 was used as a school). The two houses west of the *Zentralsauna*, one of which is said to have been "Bunker 2" (right next to the three Soviet-added barracks), don't have any numbers. This means they were neither demolished nor taken over by the Central Construction Office, so administratively they did not exist and could not be used for anything.

[85] "*Lageplan über die ausgebauten Wohnhäuser für Bombenbeschädigte BW. 166. (Eingetragen im Planausgabebuch unter Nr. 18125/29.7.44)*." RGVA, 502-2-50, p. 83.

[86] "*Baubericht für den Monat März 1942*." RGVA, 502-1-24, p. 385; "*Tätigkeits- bezw. Baubericht für den Monat März 1942*" by SS *Schütze* Jothann (*Abteilung Hochbau*). RGVA, 502-1-24, p. 398.

There is another important document which also shows that the house labelled by orthodox Holocaust historians as "Bunker 1" wasn't taken over by the Central Construction Office. This is the "Situation map of the area of interest Auschwitz Concentration Camp No. 1733" of 5 October 1942. Four buildings are shown on this map east of Construction Sector III of Birkenau, which were the homes of Józefa Wisińska, her uncle Józef Harmata, and two barns.[87] The first from the bottom (east) is said to have been transformed into "Bunker 1." Again, it has no identification number, so at that time (October 1942) houses and barns existed (like the two buildings to the west of them, next to the road fork), but they had not been taken over by the Central Construction Office, so they, too, were non-existent, administratively speaking. Hence, without identification number and *Bauwerk* number, an existing house could not be remodeled for anything, because it did not exist neither for planning nor for accounting purposes. The house relabeled to "Bunker 1" thus required these essential bureaucratic acts, such as in the case of *Bauwerk* 83, which was House no. 184 used for sanitary purposes for the troops.

In my study of the "bunkers" in Birkenau, I presented an even more germane example: a comparison with another pre-existing home which was taken over and remodeled by the then SS New Construction Office Auschwitz: No. 44, an "existing building shell," which was rebuilt as *BW* 36C and assigned as living quarters to SS-*Sturmbannführer* Cäsar, head of agricultural units. Although I have not investigated this *Bauwerk* in detail, it appears in 23 documents in my possession, invariably with its *Bauwerk* number.[88]

The "Explanatory report on the temp.[orary] expansion of Concentration Camp Auschwitz O/S," written by Bischoff on 15 July 1942, explicitly mentions *BW* 35 as a "temporary school with kindergarten" which was obtained from the "remodeling of an existing residential house." This report describes the work done and costs incurred in detail.[89]

[16] Document 16 (p. 85)

This is a work report (*Arbeitskarte*) of the inmate electrician detail regarding Order No. 636 of 9 July 1943. The authors maintain that it contains

> *"an order to reroute the electrical wire at bunker II (Sonderkommando) in connection with the expansion of sewage treatment facilities on the grounds of construction segment II."* (p. 84)

This is the document's text:[90]

---

87 Mattogno 2004a, pp. 165f. See DOCUMENTS 9 & 10.
88 *Ibid.*, pp. 36-39.
89 RGVA, 502-1-223, pp. 7, 17.
90 RGVA, 502-1-316, p. 68.

> *"Für Installation Sonderkommando-Birkenau ist folgende Arbeit auszuführen: Zuleitungskabel zum Sonderkommando verlegen/ wegen Einbau prov. Erdklärbecken im B.A.II."*
> *"For installation special unit Birkenau the following work is to be carried out: install supply wire to special unit/due to construction* [of] *temp.*[orary] *septic tank in Construction Sector II."*

Here, the authors mistranslate the German verb *verlegen*. It can have a number of distinctly different meanings, depending on the context. If people or organizations are concerned (patients, prisoners, army units, or companies, institutions etc.), *verlegen* means to move, transfer, relocate, redeploy, even to evacuate; however, if items are concerned, this verb simply means to fit, lay down (grass turfs, carpets and rugs) or to mount, to install (cables, wires, pipes, tubes, ducts).[91] If you want to make clear that an already installed wire is to be rerouted, as the authors suggest, that would be *umverlegen* or *neu verlegen* in German. In other words: the document's text does *not* suggest that an already existing wire was to be moved.

Next, the *back* of the document, unmentioned by the authors, states that no material was used (*kein Material*) and that it took 50 specialist inmate man-hours (*Häftlingsfacharbeiterstunden)* at 0.40 RM per hour as well as 120 unskilled inmate man-hours (*Häftlingshilfsarbeiterstunden*), for a total of 56 RM,[92] with the beginning and end of the work also recorded at the end of the work report (2 to 4 August 1943). In addition, this work report refers to the structure *BW* 20 of the PoW camp (Birkenau). Jean-Claude Pressac has published two blueprints of a "temporary septic tank," the first of which is dated 15 June 1943, but it refers to the "sewage-treatment plant PoW Camp, Construction Sector III, *BW* 18" (1989, pp. 169f.), which was located north of Crematorium V. In Birkenau such a sewage-treatment plant also existed in Construction Sector II (between Crematorium III and the *Zentralsauna*), as shown for example on Map No. 1991 of the Birkenau Camp dated 17 February 1943 (*ibid*., p. 220). In August 1943 construction work was certainly carried out on this treatment plant, because the "Report on the progress of work for special measures in the PoW camp and in the Main Camp," drawn up by Bischoff on 13 July 1943, states the following:[93]

> *"Temporary septic tanks for Construction Sector II. 2 pieces completely excavated, 2 more pieces 2/3 excavated. Continued brickwork for operating footbridge and for feeder channel."*

The "Activity report of the Construction Office of the concentration camp and agriculture" by SS-*Untersturmführer* Hans Kirschnek for the period from 1

---

[91] Other meanings are: to misplace/mislay an item; to reschedule/postpone/adjourn an event; to publish a book, none of which is an option here.
[92] RGVA, 502-1-316, p. 68a.
[93] RGVA, 502-1-83, p. 118.

July to 30 September 1943, which is predated 14 September 1943, does not mention the sewage-treatment plant of *BA* II in the section dedicated to the jobs carried out at the PoW camp Birkenau headlined "Special construction measures." This means that the jobs were completed by 14 September. It does contain a reference to the treatment plant in Construction Sector *BA* III, though. The plant (*BW* 18) consisted of four basins named E, F, H and I, which were all marked as completed. F was finished on 11 August, and I on 23 August.[94] The work report of 9 July 1943 thus refers to the treatment plant in Sector II. It is true that this plant was only a few hundred meters away from the site of the alleged "Bunker 2," but that does not make the authors' interpretation any less unfounded.

First, since they claim that a power wire leading to "Bunker 2" had to be moved due to the new treatment plant (the document in question doesn't even hint at this), they should show whence the wire in question came, and assuming that it was an overhead wire going in a straight line to the elusive "Bunker 2," that it crossed the area of the treatment plant.

Second, the same historians at the Auschwitz Museum claim that at the time – in July 1943 – "Bunker 2" had been decommissioned several months ago, and that no special unit was working there at that time. For example, in the voluminous general history on the Auschwitz Camp published by the Museum, Franciszek Piper writes (Piper 1999, p. 169):

> *"In the spring of 1943, gassings ceased in the two bunkers after the new gas chambers and crematoria had been completed and were being used. Bunker 1 and the barracks erected next to it were demolished or disassembled, the local burning pits were filled in and leveled. The burning pits near Bunker 2 were also leveled, and the barracks standing there were dismantled, but Bunker 2 itself was left standing. In May 1944 Bunker 2 was put back into operation and used for the extermination operation of the Hungarian Jews."*

In other words, the alleged gassings at the "bunkers" ended when the first two crematoria of Birkenau went into operation, which was on 14 March (the claimed "first gassing" in Crematorium II) and 22 March (when the camp administration took over Crematorium IV). Szlama Dragon, one of the most important "eyewitnesses," stated the following in this regard:[95]

> *"Bunker no. 1 was dismantled completely as early as 1943. After the construction of crematorium no. 2 at Brzezinka, the barracks near Bunker no. 2 were dismantled as well and the trenches filled in."*

Dragon thus confirms that the alleged homicidal activity of "Bunker 2" ceased in March-April of 1943. It is therefore absurd to claim that a link exists be-

---

94 RGVA, 502-1-27, pp. 7f.
95 Höss Trial, vol. 11, p. 106.

tween this alleged "bunker" and its purported *Sonderkommando* on the one hand and this document of 9 July 1943 on the other. I will comment more on the authors' contradictory, no-less-than-underhanded interpretations of other documents regarding the termination of activities at the "bunkers", the dismantling of the alleged undressing barracks, and the presence of the *Sonderkommando*, starting with their Document 34.

If the special unit in question was assigned to "Bunker 2", which at that time was no longer in use, it is incomprehensible why the power wire was only rerouted but not removed and recovered. This is all the more incomprehensible because previously, on 17 April 1943, Bischoff had requested that the barracks installed at "*Sonderkommando* II" be moved, a term which the authors of course interpret as "Bunker 2" (see my comments on Document 32).

Finally it should be noted that this work report refers explicitly to "*BW* 20 KGL," the high-voltage power system.

[17] Document 17 (pp. 87-90)

This is a report on the enlargement of the Birkenau Camp from 30 September 1943. The authors point out:

> *"Among the projects mentioned on the list, there is information about the remodeling of existing residential dwellings for the purpose of carrying out special operations there (twice:* Ausbau eines vorhandenen Hauses für Sondermassnahmen*) and the erection at each of them of three wooden barracks used as undressing rooms. The projects were registered in the documents under the numbers BW33 for construction segment II (bunker II) and BW33a for construction segment III (bunker I)."* (p. 86)

If this interpretation was not deliberately done in bad faith, then it reveals an astonishing ignorance of the pertinent historical documents.

The document does not constitute anything new nor is it unique. I repeat here my analysis of the question which I published in my study on the "bunkers" of Birkenau (2004a, Paragraph 3.5.2.).

<u>"House for Special Measures"</u>

This designation appears in two documents, rather late in the chronology of the "bunkers": the "Explanatory report on the construction project Concentration Camp Auschwitz O/S" of 30 September 1943, which mentions "modification of an existing house for special measures" for *BA* II and one for *BA* III at Birkenau, and the "Cost estimate for extension of POW camp of the *Waffen*-SS in Auschwitz" of 1 October 1943. Both documents also mention "3 barracks for special measures" for each house. According to Fritjof Meyer, the designation "house for special measures" is the encrypted designation of the "bunkers."[96] As I have shown elsewhere (2004b, pp. 60f.), this alleged encryp-

[96] Meyer 2002, p. 632, note 7. This reveals that not even the authors' interpretation is new.

tion actually refers to the program for the improvement of the hygienic installations of the Birkenau Camp, appropriately called "special measures for the improvement of the hygienic installations," which was ordered by SS-*Brigadeführer* Kammler in May of 1943. More specifically, the barracks "*for special measures*" bore the label *BW* 33a.

In fact, *BW* 33a was part of the inmate hospital projected for Construction Sector III of Birkenau Camp, which confirms that it had nothing to do with the alleged "bunkers." In *1942*, the relevant years for the claimed first operation period of the "bunkers," no structure had the name "House for Special Measures," and this is further confirmation of the fact that the two houses did not refer at all to the alleged "bunkers."

This is fully confirmed by the context of the document. Construction Sector III of the camp is in fact described there as follows:

"Construction Sector III:
BW 3e 114 inmate barracks Type 501/34
BW 4c 5 household barracks
BW 4e 2 household barracks Type 260/9
BW 4f 13 storage and laundry barracks Type 260/9
BW 4f 4 storage and laundry barracks Type 501/34
BW 6c 4 disinfestation barracks Type VII/5
BW 7c 11 nurse barracks (Swiss bar.)
BW 12b 12 barracks f. the seriously ill 501/34
BW 12d 2 block leader barracks Type IV/3
modification of an existing house for special measures
BW 33a 3 barracks f. special measures Type 260/9."

The authors carefully avoid drawing attention to this context, which by itself demolishes their senseless interpretation. For a discussion of this issue (the design and construction of the inmate hospital in Construction Sector III of Birkenau) I refer the reader to my dedicated study on this topic.[97]

As regards Construction Sector II, in the Explanatory Report of 30 September 1943, the existing house and the three barracks for special measures are part of *BW* 33, which comprised:

– 25 barracks for inmate property (*Effektenbaracken*) Type 260/9
– 5 barracks for inmate property Type 501/34
– modification of an existing house for special measures
– three barracks for special measures Type 260/9.[98]

Since the *Effektenlager* referred to the storage warehouses at Birkenau where the property seized from the detainees were stored, it is evident that these "special measures" were part of this area.

---

[97] Mattogno 2016c, pp. 60-72; this particular document is discussed on pp. 73f.
[98] "Erläuterungsbericht zum Ausbau des Kriegsgefangenenlagers der Waffen-SS in Auschwitz O/S." RGVA, 502-2-60, p. 81. See DOCUMENT 11.

As stated above, this raises another problem which the authors ignore completely. If, as they claim, "Bunker 2" was *BW* 33 and "Bunker 1" *BW* 33a,[99] these references should already occur in 1942 in the copious documentation on the Birkenau Camp's construction. Yet *BW* 33a appears for the first time in the explanatory report of 30 September 1943 mentioned above; *BW* 33, consisting merely of "30 barracks for inmate property", appears for the first time in a "List of structures, for buildings, exterior and auxiliary facilities for the construction project of a prisoners-of-war camp Auschwitz, Upper Silesia," dated 9 April 1943.[100]

It should also be kept in mind that the term "special measures" did not have the sinister meaning which orthodox Holocaust historiography wants to attribute to it. It referred to simple construction measures, in particular to those of hygienic-sanitary character. Following SS-*Brigadeführer* Kammler's visit to Auschwitz on 7 May 1943, a comprehensive program for the improvement of the camp's hygienic and sanitary installations was launched. In the documents this program is called either "special measures" (*Sondermassnahme*), "instant programm" (*Sofortprogramm*), "special construction measures" (*Sonderbaumassnahmen*) or even "special operation" (*Sonderaktion*). On 16 May 1943, Bischoff sent a letter to Kammler with the subject "Special measure for the improvement of sanitation facilities in the Auschwitz PoW camp."[101]

At least since 30 May 1943, Bischoff regularly sent reports to Kammler with the subject "Construction report on the special measures in the PoW camp."[102] These reports are known at least until 23 November 1943.[103] Starting with 13 July 1943, the headline changed to "Report on the progress of work on the special measures in the PoW camp and the Main Camp."[104] Among the projects described stand out those related to "disinfestation facility" and the "inmate hospital" in Birkenau's Construction Sector II and the "inmate hospital" in Construction Sector III.

In this historical and documentary context, the authors' interpretation is puerile, disconnected and specious, but it is also at odds with the dogmas of orthodox historiography.

As I pointed out earlier, by 30 September 1943 "Bunker 1" is said to have been demolished for several months and did no longer exist. How could it therefore be "remodeled"? And what's the point of remodeling it anyhow, if

---

99 Note that this is already in itself illogical, because in that case "Bunker 2" would chronologically and administratively precede "Bunker 1," since the letter "a" affixed to the number of a structure would indicate a sub-structure. For example, the crematorium in the Main Camp was labeled *BW* 11, while *BW* 11a referred to the crematorium's new chimney.

100 RGVA, 502-1-267, p. 17.

101 RGVA, 502-1-83, p. 309.

102 RGVA, 502-1-83, p. 283.

103 RGVA, 502-1-83, p. 189.

104 RGVA, 502-1-83, p. 118.

the same historians of the Auschwitz Museum declare that it was no longer used? As results from the Map No. 2503 of the inmate hospital dated 18 June 1943,[105] the building claimed to have been "Bunker 1" had been demolished, and in its location now existed the sewage-treatment plant "Temp. septic tank *BW* 18."[106] It follows that the "existing home" in Construction Sector III could only have been one of the three homes (numbered 586, 587 and 588) which appear on Map No. 2215 of March 1943 at the northern edge of the camp.[107]

As mentioned above, the "Development Map for the Erection and Extension of the Concentration and POW Camp, Map No. 2215" of March 1942 not only does *not* confirm the existence of "Bunker 2" at Birkenau, it actually proves that neither "Bunker 1" nor "Bunker 2" ever existed as such at all, that is, as existing houses taken over by the Central Construction Office and remodeled to serve as homicidal "gas chambers." Plus there is no paper trail at all for any of the work that would have been required (water supply, sewerage, construction of fences and guard towers, installation of a power line, erection of undressing barracks, transportation of materials, installation of a field railroad, road works, and all the work in a more narrow sense for creating homicidal gas chambers; see Mattogno 2004a, pp. 40-43).

[18] Document 18 (pp. 93-96)

This is the "Cost estimate for extension of POW camp of the *Waffen*-SS in Auschwitz" of 1 October 1943 which I already mentioned in my discussion of Document 17. The content is identical. In the section about Construction Sector II, the following text is written beneath *BW* 33:[108]

> *"Remodeling of an existing house for special measures: (blueprint not available)*
> *3 pcs. barracks for special measures (Type 260/9) (drawing no. 5)"*

In the section about Construction Sector III, in this document labeled "inmate hospital," we find almost the identical text:[109]

> *"Remodeling of an existing house for special measures: (blueprint not available)*
> *3 ps. barracks for special measures (Type 260/9) (drawing no. 5)"*

The authors dwell on the statement "blueprint not available" and claim:

> *"In both cases it was indicated (in what was an exception to the usual practice) that no plans had been drawn up for the buildings (*Zeichnung

---

[107] "Bebauungsplan für den Auf- u. Ausbau des Konzentrationslagers u. Kriegsgefangenenlagers, Plan Nr. 2215" of March 1943. RGVA, 502-1-94, p. 2. See DOCUMENT 13.
[108] RGVA, 502-2-60, p. 86.
[109] *Ibid.*, p. 88.

> nicht vorhanden*). This was surely in order to reduce to a minimum the number of people who knew the true purpose of the investment."* (p. 92)

This explanation is unfounded and illogical. The most sensible thing that can be inferred from this document is that the Central Construction Office had not yet ordered the staff of the surveying department to draft blueprints for the two houses. For this reason the cost estimate is only approximate for both houses: "*z.b.N.* RM 14242" (*z.b.N. = zur besten Näherung* – best approximation).

As I explained earlier, according to the historians at the Auschwitz Museum, "Bunker 1" had been demolished at the end of March 1943, hence it did not exist anymore in September 1943. *BW* 33a, which is the structure referred to with the entry "remodeling of an existing house," could therefore not have been "Bunker 1."

The blueprint for the house merely served to estimate the cost of the work. In the cost estimate in question, this calculation is based on three elements: the surface, height and cost per cubic meter. How could a blueprint like for example the one of House No. 647 in Budy (Mattogno 2004a, Document 5, p. 199), with the partition wall and the ceiling height indicated, reveal "the true purpose of the investment"? Here the authors merely suggest between the lines what they are thinking, thus inviting misunderstandings: Are they suggesting that the two houses in question were already "Bunkers" 1 and 2 at the time when this document was created (Sept./Oct. 1943)? The question should be rhetorical in nature, but the answer is not obvious at all. In fact, if the answer is yes – as it should be according to the orthodox narrative – then what were the two houses to be remodeled into? If "special measures" was a "code word" for homicidal gassings, the authors' interpretation would be senseless, because then two already existing gassing facilities would be converted into ... gassing facilities! Conversely, if in September 1943 it was planned to convert two existing houses into gassing facilities, they could have had no relationship whatsoever to the elusive "bunkers," because the Auschwitz Museum has never claimed that, in addition to the two legendary "bunkers," there existed two other gassing facilities. Hence, the inevitable consequence is that the criminal interpretation of these two documents (17 and 18) is documentarily and historically untenable. Also because, as we shall see below (comments on Document 36), the authors overlook a key element in the correct interpretation of the document.

[19] Document 19 (p. 99)

This is part of a topographical map of 28 October 1943 titled "Topographical survey to the west of Construction Sector II." The authors claim that this map shows

> *"the no longer existing forest road (*Waldweg*) running from the western edge of construction segment II to bunker II. Victims doomed to die in the gas chamber were led along this road. In aerial reconnaissance photographs from 1944, the road is visible and ends between the barracks used as undressing rooms."* (p. 98)

This argument is utter nonsense. Since the elusive "Bunker 2" used to be a residential house, it is all too obvious that it was connected by a road leading to the village of Brzezinka (Birkenau). Indeed, there were several roads. From a 1941 map it can be gleaned that three roads radiated out from the two houses located in the area of the alleged "Bunker 2." One of them was the so-called "forest road."[110] This road also appears on Map No. 2215 of March 1943 (DOCUMENT 8), where, just beyond the camp fence, the four decantation basins of the sewage-treatment plant jut out from the road.

Only the authors know what the presence of this road could possible prove. Is the mere claim that it may have led to an alleged gassing facility supposed to be proof for the facility's existence? If that were so, then any Birkenau map showing the *Hauptstrasse* (Main Street) of the Birkenau Camp leading to Crematoria II and III, and the *B Strasse* (B Street) leading to Crematoria IV and V,[111] would prove the existence of gassing facilities. That claim is absurd.

[20] Document 20 (p. 101)

These are actually two documents. The first, a letter from the SS Garrison Administration to the Auschwitz Central Construction Office of 18 March 1944, is about the installation of an alarm siren:

> *"For this purpose, we ask therefore to make available to the Camp Headquarters the wire – 4 x 6 m*[m]² *1 KV – leading to Bunker I., Birkenau, which is no longer needed."*

This is followed by the Central Construction Office's reply of 24 March 1944:

> *"The Central Construction Office is willing to make available to the camp headquarters, for the sirens' control line and on a loan basis, the wire 4 x 6 mm² which extends from the provisional supply line to Bunker I, Birkenau."*

The authors claim:

> *"This correspondence is evidence of the fact that the area where bunker I was located was not a part of ongoing extermination operations at the time, and the installations there were in the process of being dismantled and put to other uses."* (p. 100)

---

[110] RGVA 502-2-93, p. 15a. See DOCUMENT 14.

[111] Especially the Central Construction Office's Map No. 3512 of 7 February 1944, "*Absteckungsskizze der Wachtürme um das K.G.L.*" RGVA, 502-2-95, p. 19.

This conjecture contradicts the orthodox version of history as defended by the Auschwitz Museum, which is based on testimonies, according to which "Bunker 1 and the barracks erected next to it were demolished or disassembled, the local burning pits were filled in and leveled," as I have explained when discussing Document 16. If "Bunker 1" was not demolished in 1943, then the statement by witness Szlama Dragon that it had been must be declared false.

The fact is, however, that, although the alleged "Bunker 2" appears together with another building next to it on the two maps "Development Map for the Erection and Extension of the Concentration and POW Camp, Map No. 2215" of March 1943, there is no trace of the four buildings in the area around the alleged location of "Bunker 1" (DOCUMENTS 6 & 8). The latter is also not included on Map No. 2503 of the inmate hospital in *BA* III of 18 June 1943 (DOCUMENT 12). Under these circumstances, there is no doubt that in March 1944 the house called "Bunker 1" had not existed anymore for more than a year.

Regarding the fundamental "Development Map for the Erection and Extension of the Concentration and POW Camp, Map No. 2215" another childish trick of the authors should be noted, who cut off the right margin (= north) of the map so as to exclude the area of "Bunker 1" (DOCUMENT 15), just so that the reader does not notice that the same map which, according to the authors, proves the existence of "Bunker 2" with its alleged undressing barracks actually demonstrates the *non-existence* of "Bunker 1" (DOCUMENT 16).

As to the electricians detail working on Order No. 1888 of 22 August 1942 (see the discussion of Document 11), setting aside the ridiculous mistranslation of the term "lighting outlets" (*Brennstellen*) as "burning sites," orthodox historians should actually claim that this was the electric wire installed for "Bunker 1," although it would have been rather late, since this alleged gassing facility is said to have started operations almost two months earlier. It should be noted, however, that the wire in question had a cross section of 4 × 10 mm², while the one mentioned in the letter of 18 March 1944 was 4 × 6 mm², so it wasn't the same wire. The authors' interpretation of these three documents is therefore contradictory and moreover unfounded.

Document 20 shows, however, that in March 1944 there existed a "Bunker I" in Birkenau: what was it? Was this the alleged gassing facility?

This can be ruled out for various reasons.

First of all, as I stated above, the structure called "Bunker 1" by orthodox historians was demolished and no longer existed after March-April 1943, so in March 1944 the garrison administration could not refer to it as an existing structure. But since this structure existed, it could not be the legendary "Bunker 1." Given the scarcity of construction materials at Auschwitz, it is unlikely that a precious electric wire, after the structure had been demolition, was left in place and abandoned for a year rather than being immediately recovered and stored.

Second, the Auschwitz Museum has in its possession some 130,000 pages of documents created during the war by the Central Construction Office of Auschwitz. As the authors tell us in their introduction (p. 24), the museum historians have at last studied these documents carefully, and they concluded that this is the only reference to a "Bunker I" (and that there is no reference at all to a "Bunker II").

Third, in relation to alleged gassing installations, the term "bunker" was never in use among the witnesses before the end of World War II. I reiterate here what I have found on the subject in my specific study (2004a, pp. 75f.).

At the time of his Soviet deposition, Szlama Dragon, the most important witness, did not yet know the terms "Bunker 1" and "Bunker 2," allegedly used even by the SS. In this deposition he speaks always of "*gazokamera*" (газокамера) Nos. 1 and 2 and states explicitly that this was the official designation:

> *"I was taken to the gas chamber called gas chamber no. 2."*

In the later Polish deposition, the term for these alleged extermination installations becomes "bunker":

> *"This chamber was designated Bunker no. 2. In addition to it, at a distance of about 500 meters, there was another chamber, indicated as Bunker no. 1."*

The term occurs here with the same frequency as the term "*gazokamera*" in the preceding deposition. However, in this deposition Dragon is still unaware of the other two designations, "*czerwony domek*" (little red house) for "Bunker 1" and "*biały domek*" (little white house) for "Bunker 2," which were invented a few years later during the Höss trial.

The fact that in February-March 1945 the above-mentioned orthodox terminology was still unknown is also clear from the deposition of Henryk Tauber, dated 27 and 28 February 1945, in which he refers to the "bunkers" merely as "gas chambers" (газовые камеры). The same is true for the Polish-Soviet investigators who, in their report prepared between 14 February and 18 March 1945, never use the term "bunker" but speak only of "gas chambers" (газовые камеры) nos. 1 and 2.

The term "bunker" appears for the first time in the 16 April 1945 deposition of Stanisław Jankowski, which was concocted between 9 March and 16 April 1945. The necessity for a proper term for these two claimed killing facilities was obvious: in a legal procedure it was unacceptable that two buildings of the Auschwitz Camp, in which, as was alleged, hundreds of thousands of Jews had been murdered, did not even have an official name! Hence the alleged "official" designations of "Bunker 1" and "Bunker 2," where the term "bunker" was simply taken from the term sometimes used for the building of

the old crematorium of the Main Camp, which before World War II had been at times an ammunition bunker or a food-storage facility.[112]

This also explains the wide range of meanings the term had for the "eye-witnesses." For example, Henryk Mandelbaum, deported to Auschwitz on 23 April 1944, and assigned to the so-called "special unit" in early June, the term "bunker" designated, in fact, only the alleged semi-underground gas chambers of Crematoria II and III. At the trial of the Auschwitz camp garrison he declared:[113]

> *"In Crematoria III and IV* [= IV and V in today's numbering], *the gas chambers were smaller than those of Crematoria I and II* [= II and III in today's numbering]. *These crematoria were of a new kind: they could accommodate a transport of 3,000 persons. This bunker was some 50 m long and divided into two parts. In this bunker, there was a bath with showers and faucets, and a normal person entering it could believe that it was, indeed, a bath,* […]*."*

Four self-proclaimed members of the 1944 *Sonderkommando* of "Bunker 2" were interviewed by Gideon Greif in the late 1980s/early 1990s. They declared unanimously that the "bunker" was not a gassing facility but rather a cremation pit:

– Josef Sackar: When asked "Can you describe the 'bunker'?" the witness answered (Greif 1995, p. 10):

> *"Yes, it was a large pit, to which the corpses were brought and then dumped in."*

– Jaacov Gabai: (*ibid*., p. 132)

> *"Pits were arranged there to burn the corpses that the Crematorium itself could not handle. Those pits were called 'bunker.' I worked there for three days. From the gas chamber, one brought the corpses to the bunker and burned them."*

– Eliezer Eisenschmidt: (*ibid*., p. 178)

> *"They themselves then threw the corpses into the pits. The pits, or 'bunkers' as we called them, were large and deep."*

– Shaul Chasan: (*ibid*., p. 228)

> *"There was, in the area, a basin, a deep pit, which was called 'bunker'."*

It should be noted here that the German term "bunker," according to Germany's definitive dictionary, the *Duden*, has as its primary meaning a "large container for storing bulk material (e.g. coal, ore, grain)."[114] As a secondary

---

[112] Pressac 1989, p. 129; for example in "*Baubericht über den Stand der Bauarbeiten für das Bauvorhaben Konzentrationslager Auschwitz*" of April 15, 1942, one can read: "*Krematorium: Im vorhandenen Bunker eingebaut*..." (RGVA, 502-1-24, p. 320).

[113] AGK, NTN, 162, p. 165.

[114] www.duden.de/rechtschreibung/Bunker

meaning it refers to a "military shelter facility," frequently to a "shelter for the civilian population during war; air-raid shelter." As a third meaning this term refers to a prison in the vernacular.[115] It never refers to an execution facility, though.

At the end of the day, we don't know what this "Bunker I" mentioned in the discussed documents actually was. But if considering the official use of this term at Auschwitz:

– it was used for instance for Crematorium I, a former munitions and food storage building ("bunker" Meaning No. 1) later remodeled to serve as an air-raid shelter ("bunker" Meaning No. 2);
– it was used for many air-raid shelters throughout the camp (Meaning No. 2; see the discussion of Document 35 starting on p. 113 of the present study; and Document 39, starting on p. 122);
– it was used in the term "*Kartoffelbunker*" for a potato storage area (again Meaning no. 1; see my comments on Document 44 starting on p. 126);

then it is difficult to believe that it could be attributed to a normal house not used to store bulk items or as a reinforced air-raid-protection facility.

As mentioned earlier, based solely on these two documents, the authors have changed the hitherto unchallenged Arab numbers of the alleged "bunkers" to Roman numbers.

In conclusion, the presence of the term "Bunker I" in a document in no way proves that there was a "Bunker 1" at Birkenau in terms of a homicidal gassing facility, such as the presence of the term "*Gaskammer*" (gas chamber) in other documents (such as the blueprints of the disinfestation facilities *BW* 5a and 5b) does not demonstrate that homicidal gas chambers existed at Birkenau.

As is all too obvious, everything depends on the context in which these terms are found, but in the case of this "Bunker I" there is no context, because these documents only contain the term without any further explanation. It is therefore foolish to consider Document 20 a proof for the existence of the legendary "Bunker 1."

III. Section "The Barracks for Undressing at Bunkers I and II"

[21] Document 21 (pp. 105-107)

This is the well-known "Construction Report for the Month of May 1942," in which the following remark can be found among the description of work done in the PoW camp:[116]

---

[115] For instance, the basement jail in Block 11 at the Auschwitz Main Camp was generally referred to as the "bunker"; Mattogno 2005b, passim; see also p. 101 of this study.
[116] RGVA, 502-1-24, p. 263.

> *"In addition, 2 barracks (horse-stable barracks) were erected outside the PoW camp."*

The authors comment:

> *"Apart from the yard of bunker I, there was no other place outside the camp fence at Birkenau where barracks of any kind were erected at this time."* (p. 104)

This is clearly a forced conclusion of convenience but, as we shall see, it is in contrast to the Auschwitz Museum's orthodox version of "Bunker 1."

The two barracks in question are not mentioned in any other document, and they do not appear in any map of this period, so it is impossible to say with certainty where they were erected. But "outside the camp fence" did not limit the possibilities to the north-west (the direction of the alleged "Bunker 1"). In particular, the north and east sides were surrounded by buildings taken over by the Central Construction Office. About thirty houses were located near the northeast corner of the camp. They made up what was left of the village of Brzezinka, and some of them were already being remodeled in April, not to mention their "exterior" (*Aussenanlagen*), which are listed in the "Explanatory report on the construction project Concentration Camp Auschwitz O/S," written by Bischoff on 15 July 1942, which includes, among other things, two residential and work barracks (*BW* 55), and three housing barracks for labor details (*BW* 56).[117]

The two barracks in question, therefore, are not inextricably linked to "Bunker 1," as the authors claim. On the contrary. Piper says that "Bunker 1," as indicated by Czech, went into operation "already in March 1942," and he adds (referring to six testimonies) that "next to the house stood a barn and two sheds already installed during the remodeling works" (Piper 1999, p. 159). If that is so, then it follows that the two barracks were built as early as March 1942. How, then, can the authors point to "Bunker 1" as the location where the two barracks were erected outside the Birkenau Camp in the month of *May* – although they do not know where they were actually set up?

But there is another far more important issue. The authors claim that the construction report of May 1942 mentions the two alleged barracks of "Bunker 1"; if that is so, how come this document does not contain any reference to the "remodeling" of this "bunker"? This also applies to the construction report of March[118] and June,[119] the respective months when "Bunker 1" and "Bunker 2" are said to have been set up, if we follow the orthodox narrative. And why does the construction report of June contain no reference either to the three barracks allegedly installed in the course of that month as "undressing huts" near "Bunker 2"?

---

[117] RGVA, 502-1-220, p. 5.
[118] RGVA, 502-1-24, pp. 380-386.
[119] RGVA, 502-1-24, pp. 219-225.

Yet exactly for this time period the remodeling of existing structures is richly documented. The "Activity and construction report for the month of March 1942," drawn up on 1 April 1942 by SS-*Schütze* Werner Jothann, lists work done in houses no. 130, 132, 150, 152, 151 and 171, which were part of the "officers and NCOs accommodations."[120] The report headlined "Work done in the period 26 March to 25 April 1942" of the inmate painter detail describes the work carried out in House Nos. 151, 136, 1, 25, 130 and 132.[121]

From the authors' perspective, the alleged gassing facilities had very precise official names: The "bunkers" and "houses for special measures." If that was so, these structures should appear as such in the documents pertaining to the camp's construction, but they do not.

In this context, therefore, we should not be surprised by the presence of two barracks of unknown purpose somewhere outside the camp, but by the total absence of any sign about the restructuring of the alleged "bunkers."

[22] Document 22 (pp. 109), 23 (p. 111) and 24 (pp. 113-115)

These documents must be considered together, because they deal with the same matter, which I treat chronologically (see Mattogno 2004b, pp. 43-47).

On 31 March 1942, Bischoff prepared a list of structures planned as well as already constructed at Auschwitz, which the authors don't mention. *BW* 58 is described as follows:[122]

> *"5 horse-stable barracks (special treatment) 4 in Birkenau 1 in Budy."*

In the first version of this document – it bears the same date – the existence of the *BW* is announced in the following handwritten memo:[123]

> *"5 horse-stable barracks/special treatment 4 in Birkenau 1 in Bor-Budy."*[124]

A letter by Bischoff to Office C/V of the SS-*WVHA* dated 9 June 1942 (Document 22) states:[125]

> *"For the special treatment of the Jews, the camp commandant of the concentration camp, SS Stubaf. Höss, has applied orally for the erection of 4 horse-stable barracks for the accommodation of personal effects. It is*

---

[120] RGVA, 502-1-24, p. 398.

[122] "Aufteilung der Bauwerke (BW) für die Bauten, Aussen- und Nebenanlagen des Bauvorhabens Konzentrationslager Auschwitz O/S" of 31 March 1942. RGVA, 502-1-267, pp. 3-13, here p. 8; reproduced in Mattogno 2004b, Document 5, pp. 114f.

[123] "Aufteilung der Bauwerke (BW) für die Bauten, Aussen- und Nebenanlagen des Bauvorhabens Konzentrationslager Auschwitz O/S" of 31 March 1942. RGVA, 502-1-210, pp. 20-29, here p. 25; reproduced in Mattogno 2004b, Document 6, pp. 116f.

[124] The Bor-Budy area – two villages about 4 km south of Birkenau – was the location of the so-called "*Wirtschaftshof Budy*", a secondary camp, in which chiefly agricultural tasks were performed. The actual camp (men and women's secondary camp) was located in Bor.

[125] RGVA, 502-1-275, p. 56; reproduced in 2004b, Document 7, p. 118.

> *asked that the application be approved, since the matter is extremely urgent and the effects must absolutely be brought under shelter."*

On 16 June Bischoff reported to the SS-*WVHA* (Document 23):

> *"Following an oral application of camp commander SS-Stubaf. Höss, one horse-stable barrack was erected in Bor for the accommodation of female inmates."*

The "Explanatory Report on the construction project Concentration Camp Auschwitz O/S", written by Bischoff on 15 July 1942, mentions as *BW* 58 "5 barracks for special treatment of inmates."[126] The attached "Cost estimate for the construction project Concentration Camp Auschwitz , Upper Silesia" specifies, at a total cost of 75,000 RM[127] (Document 24):

> *"*BW *58 5 Barracks for special treatment and lodging of prisoners, horse-stable barracks Type 260/9 (O.K.H.)*
> *4 barracks for special treatment of prisoners in Birkenau*
> *1 barrack for the lodging of prisoners in Bor"*

The authors explain that the barrack of Document 23 was intended for the "external Kommando" at Budy-Bór (p. 110), and then they insist that of the five barracks mentioned in Document 24:

> *"four are designated for use in the 'special treatment of prisoners in Birkenau' (*Sonderbehandlung der Häftlinge in Birkenau*), that is, for the storage of property plundered from the victims of extermination ('Kanada 1'), while one is to be used in the Auschwitz sub-camp in Budy-Bór as housing for women prisoners."* (p. 112)

In their comments, the authors neither say openly that the four barracks belonged to the "bunkers" (although the documents in question appear in the section "The Barracks for Undressing at Bunkers I and II"), nor that "special treatment" was a "code word" meaning the gassing of Jews in the "bunker," so what exactly are they trying to prove by citing these documents? This only becomes clear in their comments on Document 25.

[23] Document 25 (p. 117)

This is a list titled "Distribution of Barracks" written by Bischoff on 30 June 1942 which lists all barracks planned for the construction project Auschwitz-Birkenau.

The authors assert that the document mentions

> *"three undressing barracks situated at bunker I, defined as storage barracks within the framework of the 'special treatment' operation then underway (Effektenbaracken für Sonderbehandlung). The list indicates that*

---

[126] RGVA, 502-1-220, p. 5.
[127] RGVA, 502-1-22, p. 36; reproduced in 2004b, Document 4, p. 113.

> *the functioning of not two (see document 21) but three barracks for undressing at bunker I can be dated from this moment."* (p. 116)

This comment is an intentional deception. The document lists all the barracks, sorted by type, which belonged to all sectors of the construction project Auschwitz, which in the end is summarized as follows:[128]

"I.) Prisoner-of-War Camp Auschwitz	*516 pieces*
II.) Agriculture Auschwitz	*55 pieces*
III.) SS accommodations C.C. Auschwitz	*54 pieces*
IV.) Construction depot	*24 pieces*
V.) Main camp for housekeeping Auschwitz	*2 pieces. "*

The barracks for "special treatment," however, were not part of the Birkenau Camp, but of the Auschwitz Main Camp, so they could not have any relationship with the "bunkers" at Birkenau. In fact, in the section "SS accommodations and C.C. Auschwitz" the document lists the following types of 260/9 barracks:

"1.) Barracks for personal effects erected near temp. delousing in C.C.	*4 pieces*
2.) Barracks for personal effects for special treatment	*3 pieces*
3.) Barracks for personal effects in women's C.C.	*1 piece*
4.) Accommodation barracks Bor	*1 piece"*

Therefore, of the five barracks in question, only three were specifically intended for "special treatment," although merely for storing personal belongings of inmates in the Main Camp.

The authors' implied reasoning is as follows: The four barracks mentioned in Documents 22 and 24 were erected at "Kanada I," which was structure *BW* 28, the "barracks for delousing and personal effects." The "Distribution of Barracks" mentions four barracks at this structure (called "temporary delousing"). So the authors reason that three "barracks for personal effects for special treatment" must have been something else than the above "4 barracks for special treatment of prisoners in Birkenau." For the authors, it follows that they must have belonged to "Bunker 1," which therefore had not two undressing barracks, as Document 21 seems to suggest, but three.

This reasoning is unfounded, as is its conclusion.

First of all, as is already clear from the list of Auschwitz structures of 31 March 1942 mentioned above, the structure "Kanada I," which was *BW* 28, was indeed called "reception barrack with delousing," while the five barracks for special treatment formed *BW 58*, so they had no relationship with *BW* 28. The four barracks that belonged to it were erected in June 1942, as is clear from the construction report of that month:[129]

---

[128] RGVA, 502-1-275, pp. 270-273.

[129] "Baubericht für Monat Juni 1942." RGVA, 502-1-24, p. 221.

> *"B.W. 28 temp. reception barrack with delousing*
> *Construction work has been finished. In addition, 4 prefabricated barracks (horse-stable barracks) were erected thereat."*

Next, as stated above, the distribution of barracks in question explicitly states that the three "barracks for personal effects for special treatment" were part of the construction project "SS accommodations and C.C. Auschwitz," not of the "prisoner-of-war camp" (first section of the document), so they could not belong to the elusive "Bunker I" of Birkenau.

Finally, as noted casually by the authors, their interpretation of this document contradicts their interpretation of Document 21. The latter mentions the erection of two horse-stable barracks outside the PoW camp in May, which they associate with "Bunker I." However, Bischoff's letter of 9 June 1942 (Document 22) says that on that date, "for the special treatment of the Jews, camp commandant of the concentration camp, SS-*Stubaf*. Höss, has applied orally for the erection of 4 horse-stable barracks for the accommodation of personal effects." That means these four barracks did not yet exist on 9 June, while the two barracks outside the camp existed already during the previous month. If we apply the authors' logic, this would mean that after June 1942 "Bunker 1" wouldn't have two or three, but rather six barracks!

In reality there is no doubt that the three "Barracks for personal effects for special treatment" of the "Distribution the barracks" list in question were part of the five barracks of *BW* 58, as is clear from the reference to "Accommodation barracks Bor."

[24] Document 26 (p. 121)

This is another, well-known list of barracks titled "Auschwitz Concentration Camp. Distribution of barracks" from 17 July 1942, which I published elsewhere (2004b, p. 120).

This is the authors' comment:

> *"On page 2 it is noted that a total of five type 260/9 barracks are required for carrying out the 'special treatment' operation (*Verwendungszweck-Sonderbehandlung*). Three of them had been installed as of this date, with the other two waiting to be installed.*
> *These were the barracks used for undressing at bunkers I and II. According to earlier documents, three barracks of this type were in place at bunker I at this point, and therefore the other two were to be erected next to bunker II."* (p. 120)

This reasoning is fallacious and inconsistent. The document under discussion has seven columns with the following headings: "purpose of use," "type [of barracks]," "needed," "erected," "to be erected," "stored." "pending." This is the line that interests us:

purpose of use	*type*	*needed*	*erected*	*to be erected*	*stored*	*pending*
special treatment	*260/9*	*5*	*3*	*2*	*/*	*2*

These are clearly the five barracks mentioned in Bischoff's explanatory report of 15 July 1942. In the original list they are referred to as "5 barracks for special treatment of inmates" which in turn, as we have seen, correspond to the five barracks for "special treatment" in the list of 31 March 1942. None of them, as I have demonstrated above, had any relationship with the elusive "bunkers" of Birkenau.

[25] Document 27 (pp. 123f.)

This is the "Report about the inspection of the Auschwitz Concentration Camp by SS-*Obergruppenführer* Pohl on 23 September 1942," which describes the course of the inspection: protective custody camp (=Auschwitz), construction depot, DAW (Deutsche Ausrüstungswerke workshops), delousing chamber and storage of personal effects (resettlement of Jews), new horse stable farm, Birkenau Camp.

A comparison with the detailed description of Pohl's inspection, after his visit to the DAW workshops, shows that the delousing chamber and storage of personal effects (resettlement of Jews) was identical with the "delousing chamber and storage of personal effects/Aktion Reinhard,"[130] that is, "Kanada I" (see comments on Document 14).

This resettlement of Jews corresponded to the "migration to the East" mentioned in Pohl's report to Himmler of 16 September 1942: Minister Speer needed 50,000 able-bodied workers who were to be selected at Auschwitz from the migration to the East. The document says explicitly:[131]

> *"The able-bodied Jews intended for the migration to the east will therefore have to interrupt their journey and perform armament work."*

Resettlement of Jews and migration to the east were synonyms referring to the Jewish deportation to the East via Auschwitz. According to this document, the Jews fit for labor were kept at Auschwitz, who therefore interrupted their journey, while those unable to work continued their journey to the East. This operation of keeping able-bodied Jews at Auschwitz was called "special treatment of the Jews." This "special treatment" had therefore nothing to do with mythical homicidal gassings.

[26] Document 28 (p. 127)

This is a list of structures titled "Structures of the Central Construction Office of the *Waffen*-SS and Police Auschwitz in the 3rd budget year of war." The page in question concerns the "structures which were added to the priority list

[131] BAK, NS 19/14, p. 132; see Mattogno 2004b, pp. 53, 82; Mattogno/Kues/Graf 2015, pp. 521-524.

of the defense district" (*Bauten, welche die in Wehrkreisrangfolgeliste aufgenommen wurden*) for the construction project Concentration Camp Auschwitz. The first five columns refer to "serial no.", "construction project," "GBBau Nr." (a project's ID number on the lists of the Speer ministry's construction sector), "percent complete," "total costs."

Items 20 and 21 contain the following entries:

"20 Delousing bar. a. 4 inmate property bar. VIII Za1 (1) 100% 80,000.--

21 Special tr. 5 barracks as before 100% 90,000.--"

The authors claim the five barracks for "special treatment," had been assigned as follows:

"three undressing barracks at bunker I and two at bunker II" (p. 126)

As I have shown above, such a claim is completely unfounded. The authors, among other things, forget to explain why the five barracks, if they were located at Birkenau, were part of construction project Concentration Camp Auschwitz rather than construction project PoW camp.

The "Plan of the prisoner-of-war camp of Auschwitz Upper Silesia" of 28 October 1942 shows two barracks for "inmate belongings," both at the western border of the camp, one in *BA* II, close to the southeast angle of the *Effektenlager*, the other in *BA* III, close to the first of the two morgues (*Leichenhallen*).[132]

[27] Document 29 (pp. 129-131)

This is another distribution list of barracks, dated 8 December 1942, which is a well-known document published by me (2004b, p. 121.).

On p. 3, under the heading "PoW camp," appears an entry relating to "special treatment (old)," according to which five barracks Type 260/9 were needed, five had already been erected, and none were pending. Here is the translated text of this entry:

purpose of use	*type*	*needed*	*already erected*	*pending*
special treatment (old)	*260/9*	*5*	*5*	*/*

This entry is listed under Construction Sector I, which further detracts from the authors' claim that they had been installed near the elusive "Bunkers" 1 and 2, which, administratively speaking, would have belonged to the area of Sectors II and III, respectively. These all in all (5+5=) ten barracks were most likely "Station 2 of Aktion Reinhard."

The authors' comment on this is bizarre and senseless:

"The use in this list of the term 'old special treatment site' (Sonderbehandlung alt) must certainly have resulted from the fact that, as of December

[132] "Lageplan des Kriegsgefangenenlagers Auschwitz O/S. Plan Nr. 1782" of 28 October 1942. VHA, Fond OT 31(2)/8.

> *1942, the construction of the 'new' crematoria and gas chambers was already quite advanced."* (p. 128)

The translation is misleading, because special treatment was not implemented on a "site" (in Polish: *miejsce*), but was rather a general operation. The "old" special treatment referred undoubtedly to the old special treatment procedure, which was replaced in October 1942 by the new procedure, by virtue of which the entire construction project "PoW camp Auschwitz" received the official title "implementation of special treatment" (see Mattogno 2004b, pp. 38f., 72-75). I will return to this fundamental issue when discussing Document 64.

[28] Document 30 (p. 133)

This is another list of barracks headlined "As of 7 Feb. 1943 the barracks listed below have been installed." Among other entries, it lists five horse-stable barracks for a "special unit." The authors argue that these barracks are "associated with bunkers I and II" because they "appear under the rubric '*Sonderkommando*' (*Sonder Kdo.*)." (p. 132).

Here the authors commit the same inane circular reasoning that I mentioned earlier: they assume *a priori* that the *Sonderkommando* was inextricably linked to the legendary "bunkers" without supporting this with even the vaguest documentary hint. Then they deduce from the presence of the term *Sonderkommando* the existence of the "bunkers." Their explanation is also illogical because in the document in question the term *Sonderkommando* indicates the barracks' purpose of use, as results from other entries in it, beginning with the preceding one (*Entwesung*, disinfestation). At the alleged "bunkers," however, the claimed undressing barracks were not to be used by the members of the *Sonderkommando*, if we follow the orthodox narrative, but rather as undressing huts by the inmate victims who were to be gassed.

According to the authors' logical fallacy, the purpose of use should have been "special treatment of the Jews," *i.e.*, alleged homicidal gassing, or the "old" special treatment as it appears in the list of 8 December 1942. From this list we learn that a disinfestation facility existed as part of the construction project concentration camp (Auschwitz), for which they planned five barracks Type 260/9, another one in construction project construction depot (*Bauhof*, Kanada I), which involved seven barracks of the same type, two of which were already erected and five more were to be erected. In the list of 7 February 1943 under discussion, a first disinfestation facility with five barracks is listed, a second with two, followed immediately by the "special unit" with five barracks. In this list the "special treatment (old)" of Sector BI is no longer mentioned, but not even a reference to the five still missing barracks for the disinfestation facility appears here. This indicates that the five barracks for "special unit" of this document are precisely the five barracks of the disinfestation facility that were still missing two months earlier, and that the special

unit in question was a disinfestation detail, the "special unit pest control" or "*Sonderkommando Reinhardt*" whose members worked at the "Station 2 of Action Reinhard." Their intended use was the storage of personal belongings of Jews subject to the migration to the East, as is confirmed by the next document.

[29] Document 31 (pp. 135f.)

This is a "file memorandum regarding the barracks and permanent buildings presently used for the storage of personal effects," written by Bischoff on 10 February 1943.[133]

The authors assert:

> *"At the head of the list are facilities referred to as 'Sonderkommando 1' and 'Sonderkommando II,' each of which has three adjacent stable-type barracks (now there are six of them, which means that the third barracks at bunker II had been erected over the previous few days—see document 30) used for undressing."* (p. 134)

Here they completely distort the real meaning of this document, which I outlined in another study (2004b, pp. 73f). I will reiterate and expand my elaboration here.

The quantity of personal belongings taken from the – for the most part Jewish – prisoners was huge and consequently required much space. According to a "file memorandum regarding the barracks and permanent buildings presently used for the storage of personal effects" written by Bischoff on February 10, 1943, 31 "horse-stable barracks" with a total surface area of 12,090 m² as well as four walled structures serving as storehouses with a total area of 4,306 m², thus 16,396 m² altogether, were employed for this purpose. In addition there were the 30 barracks of the so-called personal-effects storage, of which 25 had already been built, and the rest were supposed to be finished within fourteen days.

The personal-effects storage was identical with *BW* 33. It consisted of 25 "personal-property barracks Type 260/9" with dimensions 9.56 m × 40.76 m and five "personal-property barracks Type 501/34 Z.8," also called "air-force barracks," which measured 12.64 m × 41.39 m. The construction of the horse-stable barracks (Numbers 1–8 and 13–29) had begun on October 15, 1942, that of the air-force barracks (Numbers 9–12 and 30) on February 4, 1943.[134]

---

[133] "Aktenvermerk über die derzeit für die Lagerung von Effekten verwendeten Baracken und Massivgebäude," RGVA, 502-1-26, pp. 33f.

[134] – "*Bauantrag* zum *Ausbau des Kriegsgefangenenlagers der Waffen SS in Auschwitz O/S. Errichtung von 25 Stck. Effecktenbaracken. Erläuterungsbericht und Kostenvoranschlag*", March 4, 1944. RGVA, 502-1-230, pp. 95-97.
– "*Bestandsplan der 25 Effektenbaracken*", October 20, 1943. RGVA, 502-1-230, p. 100.
– "*Bauantrag zum Ausbau des Kriegsgefangenenlagers der Waffen SS in Auschwitz O/S. Errichtung von 25 Effektenbaracken BW 33. Erläuterungsbericht Kostenvoranschlag*", March 4,

Since the personal-effects storage was intended specifically to accommodate personal belongings of prisoners, as soon as it came into operation, the 31 horse-stable barracks initially allocated for this purpose became free for other uses. This is crucial in order to understand the true meaning of the following documents.

According to Bischoff's file memo of 10 February 1943, the following barracks were still available "for the storage of personal effects":[135]

"1. At Special Unit 1, 3 horse-stable barracks
2. At Special Unit 2, 3 horse-stable barracks."

The document explicitly says that these barracks were intended to store personal belongings of prisoners, but then how can the authors seriously claim that these six barracks were used as undressing huts near the elusive "bunkers"? Here, as elsewhere, this is a matter of bad faith, as is reflected further by the fact that they are silent about other documents confirming my interpretation.

In a 1999 article, German orthodox scholars Bertrand Perz and Thomas Sandkühler drew attention to the personnel files of some SS NCOs transferred to Auschwitz in 1942 as part of Operation Reinhard (Perz/Sandkühler 1999, pp. 283-318; see Mattogno 2008, pp. 24-31), a fact confirmed by the authors' Document 61 (p. 221), which lists 12 SS men transferred from Dachau to Auschwitz "for Operation Reinhard." Perz and Sandkühler write (*ibid.*, p. 296):

> *"Kühnemann* [136] *was deployed exclusively at the operation 'resettlement of the Jews,' where he was in charge of supervising, sorting and storing the belongings accumulating at* So.[nder]K[omman]do. *I and Crematorium II."*

The source given by Perz and Sandkühler is a "certificate of service" (*Dienstleistungszeugnis*) of 30 March 1943 (*ibid*., p. 314, note 110). They also inform us that SS-*Hauptscharführer* Georg Höcker "watched *Sonderkommandos* I and II and the delousing chambers 1 and 2" (*ibid*., p. 314, note 113). They also quote the following note by SS-*Sturmbannführer* Willi Bürger, head of the camp's Section IV – Administration (*ibid*., p. 296):

> *"As of 25 September 1942, SS*-Hauptscharführer *Höcker carries out his duty at the administration CC and SS garrison administration Auschwitz.* [...] *He was entrusted with supervising the* Sonderkommando *and the disinfestation chamber. He was moreover employed as deputy head of the admin-*

1944. RGVA, 502-1-230, pp. 103-105.
– "*Bestandsplan der Effektenbaracke – Type Luftwaffe*", October 22, 1943. RGVA, 502-1-230, p. 108.

[135] RGVA, 502-1-26, p. 73.

[136] SS-*Unterscharführer* Heinz Kühnemann was administrator of inmate belongings (*Effektenverwalter*).

> *istration of inmate property. From end of September until mid-November 1943 Höcker supervised Disinfestation Chamber I."*

The context of the document under review is therefore unequivocally that of storage and pest control of Jewish property: the connection between *Sonderkommando* I and II on the one hand and "storage of personal effects" and "disinfestation chambers" on the other confirms that the *Sonderkommando* I and II in question had nothing to do with any alleged homicidal gas chambers, but had to do precisely with pest control.

Franciszek Piper commented as follows about this (Piper 1995, p. 181):

> *"Initially, until the commissioning of the 'Kanada I' warehouses, the personal belongings of gassed inmates were stored in the Deposit Warehouses at the Main Camp. These warehouses located next to the DAW workshops, including the disinfection chamber, were surrounded by a barbed-wire fence and were constantly guarded by SS guards on watchtowers. The SS man Wladimir Bilan was the first head of these warehouses, then Georg Höcker since October 1942* […]*."*

As Andrzej Strzelecki confirms, this refers to "Kanada I," whose former head was Wladimir Bilan (Strzelecki 1999, p. 199). Hence Höcker was the head of this storage area precisely since October 1942.

Strzelecki also states that neither Kühnemann nor Höcker has ever been accused by witnesses of having been involved in any extermination activities (*ibid.*, p. 140). This is not quite true, though, because Höcker is mentioned as "*Hauptscharführer* and head of disinfestation I Auschwitz I"[137] as well as an alleged "murderer" in a list of former SS men from various concentration camps drawn up on 16 December 1946 by former Auschwitz inmate Adolf Rögner. Kühnemann appears there as "*Unterscharführer*, disinfestation I Auschwitz I," with his alleged "crimes" being thuggery and denouncing Jews.[138]

Finally, the relationship between the belongings of prisoners and Crematorium II remains to be explained. In March 1943 the situation of storing the belongings of the deported Jews was catastrophic, as is clear from a letter by Bischoff to Kammler dated 2 March 1943 with the subject "installing disinfestation barracks," in which we read:[139]

> *"As can be seen from the letter of the Central Construction Office to the Commandant of the CC, everything possible has been done on this side to provide accommodation for the accumulating effects. If clothing and other items accruing from the transports are stacked in the open, then this is only*

---

[137] Which confirms that the "Entwesungs- u. Effektenkammer Aktion Reinhard" – *i.e.* "Kanada I" – was identical with "Station 1" of "Aktion Reinhardt."

[138] "SS-Beurteilungsliste von ehemaligen SS-Angehörigen verschiedener Konzentrationslager, Auschwitz I, II, III, Dachau, Mauthausen, Melk und Ebensee i/S." AGK, NTN, 118, p. 10, 5.

[139] RGVA, 502-1-336, p. 77.

> *due to their improper storage, for which the administration of the concentration camp is responsible. If a major part of the effects stored outdoors is lost due to the weather, then this office cannot be blamed for this at all."*

In this situation, the most-likely scenario is that some of the personal effects had been provisionally deposited outdoors near Crematorium II, which had one of the largest open spaces of the entire camp, awaiting the pending entry into operation of the new *Effektenlager*, which was located in the same western sector of the Birkenau Camp where this crematorium was located.

Document 32, which we will discuss next, fully corroborates the interpretation set out above.

In this context, the authors overlooked an important document published several years ago by the Auschwitz Museum, which in fact mentions the term *Sonderkommando* I and II (see DOCUMENT 18). It is from the officer on duty, dated 9-10 December 1942.[140] Here I translate only the most important parts:

> *"At 12:25 it was reported that 6 inmates had fled from Sonderkommande I* [sic...]. *At 20:30 Harmenze* [sic] *called that 2 inmates were apprehended.* [...] *These were the two Jewish inmates N 36816 + 38313 who had fled early on 7 Dec. 42 from Sonderkom. II."*

In her *Auschwitz Chronicle*, Danuta Czech summarizes the reviewed document as follows in an entry of 9 December 1942 (1990, p. 282):

> *"At 12:25 P.M., the Guard Commander receives the report that six prisoners have escaped from the Special Squad."*

She then states that "[t]he two Jewish prisoners, Nos. 36816 and 38313," fled "from Special Squad II." For 10 December she adds (*ibid.*):

> *"The two Jewish prisoners, Ladislaus Knopp (No. 36816) and Samuel Culea (No. 38313), who escaped from the Special Squad on December 7, are locked in the bunker of Block 11 and released from the bunker to the camp the same day.*
>
> *Two Jewish prisoners who escaped from the Special Squad the previous day are captured and sent to the bunker of Block 11. They are Bar Borenstein (No. 74858), born February 10, 1920; and Nojech Borenstein (No. 74859), born March 25, 1925, in Szreńsk.* [...] *The two of them are probably executed publicly on December 17 in the presence of the Special Squad to terrorize the other prisoners.*[**] *"*

In a footnote Czech explains (*ibid.*):

> *"[**] Next to the names of the two prisoners and the entry 'released' is the letter 'Ü'."*

---

[140] The document gives as its date "9/10.42," but this cannot be the 9th of October, but must be the night from the 9th to the 10th of December (the month, missing in the date, is given in the report's text). This is the night spanning the two days when the officer in question was on duty (judging from the mentioned hours, probably from 12.00 on the 9th to 12.00 on the 10th).

It is unclear why the author of the *Auschwitz Chronicle* assumes that these two prisoners were executed, since "Ü" usually was short for "*überstellt*" – transferred. In fact, the numbers of these detainees are not included in the list of deceased inmates of the morgue register of Block 28 of the Main Camp – neither for 9 December 1942 nor for any of the following days.[141]

It is not even clear why the two pairs of Jewish inmates are supposed to have been treated so differently: the first pair was released back into the camp, while the second pair is assumed to have been killed. As for the first pair, the names of Ladislav Knapp [sic] and Samul Culer [sic] are listed in the fragment of the camp's card index as copied by the former prisoner Otto Wolken. According to this, Knapp belonged to *Sonderkommando* II, while the other was employed at a *Sonderkommando*. For both, their cards show under "changes": "*15:12:42 abg. am 10:12:42 abgesetzt / Flüchtling /.*"[142] The term "*abgesetzt*" means that the two detainees' entries had been suspended from the card index; the abbreviation "*abg.*" could mean "*abgegeben*," handed over, *i.e.* reassigned to the inmate-labor-deployment authorities. It is certain, however, that the two detainees were not killed, because the words "*verstorben*" (deceased) are missing, as occurs for instance for the two prisoners preceding the entry of Knapp: the Slovak Jews Eduard Tintner, no. 36682, "died 22 June 1942" (*verstorben 22.06.42*), and Alfred Timföld, no. 36810, "died 16 June 1942" (*verstorben 16.06.42*).[143]

This is confirmed by the list "Arrivals of 23 May 1942, transferred from CC Lublin," which includes 1,000 detainees with serial number, first and last name, date and place of birth, as well as date of death. The vast majority of these prisoners died during August 1942, but Ladislav Knapp was one of the few survivors, while Alfred Timföld died on 16 June 1942.[144]

Had Knapp, Culer and/or the Borensteins really been part of any *Sonderkommando* tied to homicidal activities at the "bunkers," these prisoners who had dared to escape would have been killed without mercy, if the orthodox narrative were true.

The most important aspect of Wolken's record referred to above is the fact that Czech omitted the Roman number of the *Sonderkommando* from which six detainees had fled: "I." The reason is easily understood. In her entry for 3 December 1942 she writes (1990, pp. 277f.):

> *"The approximately 300 Jewish prisoners in the special squad who dig up and burn the 107,000 bodies buried in mass graves are taken from Birkenau to the main camp by the SS. There they are led to the gas chamber in*

---

141 AGK, *Leichenhallenbuch*, Collection "OB," 385, pp. 42f. and following.
142 AGK, NTN, 149, pp. 142f., serial numbers 2083 and 2092.
143 *Ibid.*, p. 142, serial numbers 2081 and 2082.
144 APMO, Fot. 423, pp. 142f.

Crematorium I and killed with gas. Thus the witnesses to the corpse burning are disposed of."

For 6 December 1942 she notes (p. 280):

"A new Special Squad is formed to which several dozen Jewish prisoners, selected from Section B-Ib, are assigned. It is probably called Special Squad II; some of those assigned to it are Meilech (Milton) Buki (No. 80312) and Szlama Dragon (No. 80359) [...]. *In the trial against Rudolf Höss, he* [Szlama Dragon] *appears as a witness and charges that the group of Jewish prisoners was sent to the Special Squad on December 9 and employed in incinerating corpses for several days thereafter. On the other hand, the camp documents indicate that the Special Squad* [II] *must have already been in existence when prisoners who were working in it made attempts to escape on December 7 and 9."*

Her reference to "camp documents" most likely points at the above-mentioned report by the officer on duty filed on 9 December 1942.

In summary, the *Sonderkommando* allegedly exterminated on 3 December 1942 is said to have been replaced by a *Sonderkommando* II on 6 December, which means the first one was *Sonderkommando* I. Czech claims that the prisoners who escaped on 7 and 9 December all came from *Sonderkommando* II, but the report by the officer on duty explicitly says that the six detainees in question had been employed in *Sonderkommando* I. By omitting the number "I" in her entry on 9 December and by falsely asserting in her entry on 6 December that all escaped prisoners came from *Sonderkommando* II, Czech tried to conceal the fact that on 9 December 1942 both a *Sonderkommando* I *and* a *Sonderkommando* II existed simultaneously, which destroys her fallacious reconstruction. It is all too obvious that, if the two *Sonderkommandos* existed at the same time, the first could not have been exterminated several days earlier, and the second could not have taken its place a few days later.

Czech's deceptions aimed at giving credence to the thesis that *only one Sonderkommando* existed at Auschwitz which worked in the crematoria, and it had to be the only one, because, as I explained above, its very name pointed at its alleged duty of cooperation in the claimed *Sonderbehandlung*. It is clear that the editor of the *Auschwitz Chronicle* was forced to resort to this deception because at that time (1989/1990) no document was known which established a relationship between the *Sonderkommando* and the crematoria.

The Auschwitz Museum has since published a document on its website, which, as far as I know, is the only one unequivocally establishing this relationship: the "escape report" of 7 September 1944 (see DOCUMENT 19).

Transcript:

Pezula, Constable of the Protective Police d.A. [?]
c) 7 Sept. 44. 19:15 AM Wilczek
[Column 2]
Escape report.
Around 1400 hours today, a large number of prisoners escaped from the C.C. Auschwitz II, from the Sonderkommando (crematorium), mostly Jews. Some of the fugitives have already been shot during the instantly initiated pursuit. The search operation continues.
Features: shaved, no. tattooed on the l.[eft] forearm. Clothing: partly civilian with red stripes. I request to instantly carry out further search measures a.[nd] to inform subordinate offices.
There are only 4 inmates left on the run.
[Column 3]
Reinforced patrol sent to the railway station area."

This document tells us that there was a *Sonderkommando* even at the crematorium, but this was just one of many *Sonderkommandos* existing at Auschwitz. This is even confirmed indirectly by the document itself, because the fact that it specifies in parentheses that they had escaped from the *Sonderkommando* of the "crematorium" implies that there were also other *Sonderkommandos*. Even the fact that only "most" of the escapees from this *Sonderkommando* were Jews contradicts the orthodox Holocaust narrative, according to which basically *all* members of the *Sonderkommando* at the crematoria were Jews.

[30] Document 32 (pp. 139)

This is a letter by Bischoff to the Camp Commandant dated 17 April 1943 with the subject "Allocation of horse-stable barracks on a loan basis." There is

nothing new about this either, as I examined this document already elsewhere (2004b, pp. 73f.). It states:[145]

> *"The horse-stable barracks erected at Special Unit II and at Crematorium III are urgently needed for troop accommodation in Birkenau and for the infirmary in Construction Sector II. After the operation of Special Unit II has stopped and the corresponding rooms at Crematorium III are available as well, information is requested as to when the barracks can be dismantled, so that they can be erected at the determined places as soon as possible."*

The authors claim that *Sonderkommando* II refers to the inmate detail working at "Bunker II" and that the entry relating to Crematorium III is erroneous and should be Crematorium II instead. Then they add:

> *"An extant map of the camp from March 20, 1943 shows the location of the barracks next to the north wall of crematorium II. It served as a provisional undressing facility before the completion of the underground rooms designated for this purpose."* (p. 138)

The first interpretation, as I noted above, is completely unfounded: *Sonderkommando* II was referring to the storage of personal effects confiscated from the deportees, and was therefore unrelated to the chimeric "Bunker II." The activity of *Sonderkommando* II had ceased because, as explained in the file memo of 20 February 1943, the new Birkenau *Effektenlager* went into operation in late February/early March 1943.

The second interpretation is equally unfounded. It should be noted right away that the map of 20 March 1943 (reproduced by the authors on their p. 140) had already been published by Jean-Claude Pressac, as will be seen. He meant to use it in order to undergird Henryk Tauber's declaration which attributed a murderous purpose to this shed, a claim embraced by the authors. On this issue there are again a number of other fundamental documents which the authors ignore. I reiterate here a slightly updated version of my exposé published in another study (2019, pp. 67-73).

On 21 January 1943, the SS garrison surgeon of Auschwitz, SS-*Hauptsturmführer* Eduard Wirths, wrote a letter to the camp commander:[146]

> *"1. The SS garrison surgeon at Auschwitz requests to install a partition in the dissecting hall planned for the new crematorium building at Birkenau, dividing the hall into 2 rooms of equal size and to have 1 or 2 wash basins installed in the first of these rooms, because the latter will be needed as an autopsy room, whereas the 2nd room will be needed for anatomical preparations, for the preservation of files and writing materials and books, for*

[145] "Leihweise Zurverfügungstellung von Pferdestallbaracken Typ 260/9." RGVA, 502-1-79, p. 119.
[146] RGVA, 502-1-313, p. 57.

the preparation of colored tissue sections and for work with the microscope.

2. Furthermore it is requested to provide for an 'undressing room' [Auskleideraum] *in the cellar rooms."*

Highly important conclusions for our topic derive from this letter. Before setting them out, we must outline the implications of the alleged decision to transform *Leichenkeller* 1 of Crematoria II and III into homicidal gas chambers.

If we follow Pressac, the Central Construction Office decided in November 1942 "to equip the crematoria with homicidal gas chambers" (1993, p. 66). This decision is said to have begun to permeate the crematoria projects such as Blueprint No. 2003 of 19 December 1942. Because a ventilation with aeration and de-aeration had been planned only for *Leichenkeller* 1, it is clear that this room had to become the homicidal gas chamber. And because it was planned to implement mass exterminations, it is also clear that *Leichenkeller* 2 had to be turned into the undressing room for the future victims, in keeping with the procedure already tried out – according to Pressac – in Crematorium I. Hence, the decision to transform *Leichenkeller* 1 into a homicidal gas chamber implied the decision to transform *Leichenkeller* 2 into an undressing room, and the two decisions were taken at the same time.

This having been said, let us go back to the letter discussed above, from which we derive:

1. The decision to create an undressing room in the crematorium was taken neither by the *Kommandantur* (the camp commander, *i.e.* Höss) nor by Central Construction Office (Bischoff) but by the SS garrison surgeon.
2. The garrison surgeon did not specify anything in particular in his request, presenting it as a mere afterthought to the sanitary and hygienic requirements set out for the autopsy room.
3. In hygienic and sanitary matters, as well as in matters relating to pathology and forensic medicine, the crematorium was attached to the garrison surgeon who knew the corresponding projects very well and occasionally intervened – as in this case – with the Central Construction Office asking for modifications.
4. The letter cited demonstrates that the SS garrison surgeon was completely unaware of the alleged plan to change *Leichenkeller* 2 into an undressing room for the victims to be gassed: he requested for an undressing room to be provided, in a very general way, "in the cellar rooms" without specifically mentioning *Leichenkeller* 2 or excluding *Leichenkeller* 1 for this purpose. However, in view of his position, the SS garrison surgeon could not have been unaware of a decision, allegedly taken three months earlier, to create an undressing room in *Leichenkeller* 2, because otherwise, considering his position in the camp hierarchy, such a decision could not actually

have been arrived at. Yet as results from the above document, the idea of an undressing room was conceived by the SS garrison surgeon only in January 1943 and conveyed to the Auschwitz camp commander on January 21st.

On 15 February, Janisch replied to the SS garrison surgeon's letter by a handwritten note stating:[147]

"item 1.) has been arranged for.
item 2.) for undressing, a horse-stable barrack has been erected in front of the cellar entrance."

Why should a crematorium have an undressing room? And why was a barrack built for such a purpose?

Pressac has noted that a horse-stable-type barrack in front of the crematorium does indeed appear on the map entitled "Situation map of the PoW Camp Auschwitz O/S" dated 20 March 1943. It is at the location mentioned by Janisch, *i.e.* "in front of the cellar entrance." Pressac writes (1989, p. 462):

"The drawing confirms the erection of a hut of the stable type in the north yard of Krematorium II in March 1943. We know little about this hut, except that after serving as an undressing room for the first batch of Jews to be gassed in this Krematorium, it was quickly dismantled – only a week later according to the Sonderkommando witness Henryk Tauber. The first mention of an access stairway through Leichenkeller 2 found in the PMO archives, BW 30/40, page 68e, is dated 26/2/43 (Document 7a). As soon as this entrance was operational, the undressing hut was no longer required."

Pressac treats the matter also elsewhere, but provides a different reasoning (*ibid*., p. 227):

"On Sunday 14th March, Messing continued installing the ventilation of Leichenkeller 2, which he called 'Auskleidekeller II/Undressing Cellar II.' In the evening, about 1,500 Jews from the Cracow ghetto were the first victims to be gassed in Krematorium II. They did not undress in Leichenkeller 2, still cluttered with tools and ventilation components, but in a stable-type hut temporarily erected in the north yard of the Krematorium."

He later comes back to the first interpretation (*ibid.*, p. 492):

"This Bauleitung source confirms the erection in mid-March 1943 of a hut running south-north in the north yard of Krematorium II, which was used, according to Henryk Tauber, as an undressing room, apparently because the access to the underground undressing room (Leichenkeller 2) was not yet completed."

Pressac refers to the following statement by Henryk Tauber:[148]

---

[147] RGVA, 502-1-313, p. 57a.

[148] Minutes of the deposition of Henryk Tauber dated 24 May 1945, before the investigating Judge Jan Sehn. Höss Trial, vol. 11, pp. 122-150, here, p. 136.

> *"They* [the alleged victims] *were pushed into a barrack which then stood perpendicular to the building of the crematorium on the side of the entrance to the yard of crematorium no. II. The people entered into this barrack through a door located near the entrance and went down* [into the half-basement of the crematorium] *along steps which were to the right of the Mühlverbrennung* [sic] *(garbage incinerator). This barrack was used at the time as an undressing place. But it was used for more or less one week and was then dismantled."*

Pressac publishes Map 2216 of 20 March 1943 in its entirety, but with illegible writing (*ibid.*, p. 226). However, he points out a detail from another version of this map (corresponding to another negative at the Auschwitz Museum) in which the entries are clearly visible (*ibid.*, p. 462). The barrack in front of the crematorium is shown as a light-colored rectangle, a symbol which corresponds neither to a finished barrack, which would have been a dark rectangle, nor to a barrack under construction, which would have had diagonal hatching, but to a planned barrack. This shows up even more clearly in another detail of this map also published by Pressac (*ibid*., p. 256).

There is, moreover, yet another map of Birkenau, drawn up immediately prior to the one shown by Pressac, in which the barrack in question does not appear at all. It is the "Development Map for the Erection and Extension of the Concentration and POW Camp, Map No. 2215" dated March 1943 (see Note 71 on p. 73). As it has the number 2215, it was prepared immediately before the one numbered 2216, and therefore dates from 20 March 1943 or before.

It is not clear why this barrack appears only on Map 2216. Even though it had already been erected in front of Crematorium II on 15 February 1943, it is not indicated on map 1991 of 17 February, which otherwise shows barracks planned, under construction, and finished (Pressac 1989, p. 220). This is probably due to its being an emergency stop-gap measure. One does not know when the barrack was taken down. What is certain, however, is that the erection of this barrack had nothing to do with the alleged homicidal gassings.

Pressac's first explanation – that the barrack was erected because access to *Leichenkeller* 2 was not yet ready – does not hold much water. Speaking of Crematorium III, he affirms that work on the entrance to *Leichenkeller* 2 of Crematorium III began on 10 February 1943, and that for Crematorium II the only reference to the realization of an entrance is dated 26 February, which according to Pressac would lead us into an irresolvable paradox (1989, p. 217). In fact, there is no paradox, because Pressac's dates for Crematorium III are wrong. On 14 March 1943, the entrance was perfectly serviceable, and there would therefore have been no need for an undressing barrack.

On 20 March 1943, the day on which map 2216 was being prepared, the SS garrison surgeon at Auschwitz, in a letter to the camp commander, men-

tioned the removal of the corpses from the detainee hospital to the crematorium.[149] This makes the matter very clear. The SS garrison surgeon was worried about the poor sanitary and hygienic conditions in which the corpses of the detainees were kept on account of the inadequacy of the then existing morgues. These were simple wooden sheds which could not keep rats from feeding on the corpses, with the risk of an outbreak of the plague, as he writes clearly in his letter of 20 July 1943[150] about a situation which must already have existed in January.

The SS garrison surgeon thus intended to have the corpses taken to a safer place, from a sanitary point of view, and the best places were obviously the two morgues of Crematorium II which, at that time, was the farthest advanced. On 21 January 1943 he requested the provision of an undressing room for these corpses "in the cellar rooms" of Crematorium II. On 29 January, Bischoff replied that the corpses of the detainees could not be placed in *Leichenkeller* 2, but said that this was irrelevant because they could be placed in the *Vergasungskeller* instead.

On 15 February Janisch informed the garrison surgeon that "a horse-stable-type barrack in front of the cellar entrance" had been erected at Crematorium II as an undressing room for the corpses. This barrack was therefore built between 21 January and 15 February, and for that reason alone it could not have had a criminal purpose. This is confirmed by the fact that Crematorium II went into operation on 20 February 1943. A report by Kirschnek dated 29 March 1943, states the following about this crematorium:[151]

"Brickwork completely finished and started up on 20 February 1943."

Thus, the crematorium went into operation even before the ventilation had been installed in *Leichenkeller* 1, which means that it received corpses even before that room could theoretically have been used as a homicidal gas chamber. But why then was an outdoor barrack needed? The answer is simple. On 11 February 1943 – four days before the date of Janisch's reply to the SS garrison surgeon – work on the installation of the ventilation equipment in *Leichenkeller* 1 had begun,[152] and therefore this room was no longer available as an undressing room. Besides, *Leichenkeller* 2 was not operational either from January 1943 onwards. In "Report no. 1" from Bischoff to Kammler dat-

[149] Letter from SS-Standortarzt to the Commandant of CC dated 20 March 1943, concerning "Häftlings-Krankenbau – KGL." RGVA, 502-1-261, p. 112.

[152] APMO, BW 30/31, p. 30.

ed 23 January on the subject "Crematoria PoW camp, state of advancement" we can read:[153]

> *"Cellar II. Reinforced-concrete ceiling finished, removal of planking subject to weather conditions."*

In his report dated 29 January 1943, Prüfer confirmed:[154]

> *"Ceiling of Leichenkeller 2 cannot yet be freed of planking because of frost."*

On the same day, Kirschnek confirms in a file memo:[155]

> *"Leichenkeller 2 basically finished, except for removal of planking from ceiling, which can only be done on days without frost."*

Finally, as we have already seen, Bischoff informs Kammler in his letter of 29 January 1943:[156]

> *"The Reinforced-concrete ceiling of the Leichenkeller could not yet be freed of its planking because of frost conditions."*

During the first week of February 1943, average temperatures at Krakow were below –5°C, and during the second week below 0°C (Setkiewicz 2011b, p. 59), which makes it highly likely that *Leichenkeller* 2 remained non-operational for some time longer because of the impossibility to remove the form planks from the concrete.

On 8 March 1943, Messing, the technician, began to install the ventilation duct in *Leichenkeller* 2, which he regularly calls "undressing cellar" in his weekly work reports.[157] The work was finished on 31 March 1943 ("de-aeration system undressing cellar installed").[158] Therefore, already by 8 March the Central Construction Office – acting on the request of SS garrison surgeon – had decided to create an undressing room in the half-basement of Crematorium II, more specifically in *Leichenkeller* 2. As against this, *Leichenkeller* 1 became operational as of March 13 ("aeration and de-aeration systems of cellar 1 put into service").[157] On 20 March, the day of the alleged gassing of 2,191 Greek Jews (Czech 1990, p. 356), the SS garrison surgeon was occupied only with the removal of the corpses of detainees from the camp hospital to Crematorium II without any reference to any alleged gassing victims.

We now have the answers to the two questions raised in the beginning:

1. The undressing room was used for the corpses of the detainees who had died in the camp. At the Belsen trial, SS-*Hauptsturmführer* Josef Kramer,

[157] Arbeitszeit-Bescheinigung of Topf for the period of March 8-14, 1943. APMO, D-ZBau/2540, p. 26.
[158] *Ibid.*, p. 23.

commander of the Auschwitz Camp from May 8, 1944, declared in this respect (Phillips, p. 731):

> *"Whoever died during the day was put into a special building called the mortuary, and they were carried to the crematorium every evening by lorry. They were loaded on the lorry and off the lorry by prisoners. They were stripped by the prisoners of their clothes in the crematorium before being cremated."*

2. Initially a barrack set up in front of the crematorium was used as undressing room, because *Leichenkeller* 2 was not yet operational on 21 January 1943, the day the SS garrison surgeon requested an undressing room; *Leichenkeller* 1 was available from 11 February.

The existence of an undressing room in the crematorium is therefore entirely normal, as results moreover from the assignment of rooms in Crematorium I of the Main Camp: Laying-out room (*Aufbahrungsraum*), corpse washing room (*Waschraum*) and morgue (*Leichenhalle*). As the corpses were cremated without a coffin, the Laying-out room was not a "hall for the placement of the corpse on a stretcher" but a room in which the bodies were undressed before being washed in the room next door and finally placed naked in the morgue.

This exposé deals with the building appearing on Map No. 2216 of 20 March 1943, but that does not mean that Bischoff's letter of 17 April 1943 (Document 32) refers to it, erroneously mentioning twice Crematorium III instead of Crematorium II. Because this building was dismantled after just a week, hence toward the end of March, if we follow the orthodox Holocaust authority Henryk Tauber, we have to assume that Bischoff was referring precisely to Crematorium III. Although it was in an advanced stage of construction at that time, this crematorium became operational only on 26 June 1943. This means that one or more shacks erected near it before 17 April could not have had a criminal purpose. Their purpose could simply have been for the temporary storage of crematorium or construction equipment. When "the corresponding rooms at Crematorium III" were available for their intended purpose, the barrack was dismantled (or the barracks).

[31] Document 33 (pp. 143-145)

On 7 May 1943 Kammler visited Auschwitz. At 20:15, at the *Führerheim* (officers' hall), he had a meeting with six SS officers, SS-*Obersturmbannführer* Höss, commandant of the camp, SS-*Obersturmbannführer* Möckel, head of the SS garrison administration, SS-*Sturmbannführer* Bischoff, head of the Central Construction Office, SS-*Sturmbannführer* Caesar [Cäsar], head of agricultural units, SS-*Hauptsturmführer* Wirths, garrison surgeon, and SS-*Untersturmführer* Kirschnek, head of the construction office C.C. Auschwitz and agriculture Auschwitz.

After that meeting, Bischoff wrote a file memo on 9 May which the authors present as their Document 33. As point i), under the heading "Agricultural Construction," it states:[159]

> *"i. Stable farm Birkenau:*
> *Two horse-stable barracks from 'Special Operation 1' are erected in addition to one Swiss and one air-force barrack. While all agricultural structures are now to be finished in sequence with massive efforts, erecting these barracks is particularly urgent."*

The authors first decree that "Special Operation 1" was "Bunker I," then explain:

> *"Documents 32 and 33 indicate that bunkers I and II were withdrawn from use in May 1943. In the light of the entry into operation of the new crematoria and gas chambers in the first half of 1943, there were probably plans for the dismantling of both bunkers. It seems, however, that the malfunctions of the crematoria that occurred at the turn of May/June 1943, which could potentially result in the suspension of the extermination of the Jews, led to the abandonment of these plans."* (p. 142)

From this document we can actually infer on the one hand that there was at least one "Special Operation 2," and on the other hand that "Special Operation 1" had more than two barracks. It is therefore clear that "Special Operation 1" corresponded to the activity of *Sonderkommando* 1 at the three barracks for inmate property (*Effektenbaracken*) assigned to it, and that *Sonderkommando* 2 was in service at "Special Operation 2." And if "*Sonderkommando* 2" had gone out of business on 17 April 1943, and on 9 May two of the three barracks of "Special Operation 1" could be put to another use,[160] this resulted obviously from the fact that the 30 barracks of the *Effektenlager* were ready for use since late February/early March 1943, as I pointed out above.

[32] Document 34 (p. 147)

This is a letter by Bischoff to the head of the SS garrison administration, SS-*Obersturmbannführer* Karl Ernst Möckel, dated 4 February 1944, stating:

> *"For carrying out a special measure, I once made available 3 horse-stable barracks from Construction Sector III of the PoW camp on a loan basis. After the crematoria have been completed long time ago and have been handed over to your administration, the above-mentioned barracks allocated on a loan basis are no longer needed at* Sonderkommando *I. The barracks were meant for a specific purpose and must be set up in the Construction Sector III of the PoW camp.* [...]

---

[159] RGVA, 502-2-117, p. 6.

[160] Both documents speak of "horse-stable barracks," as in the file memo of 10 February 1943 in relation to *Sonderkommando* 1 and 2.

> *I have given orders that the barracks are to be dismantled at* Sonderkommando *I and are to be set up in Construction Sector III."*

According to the authors,

> *"This passage indicates that bunker I and its three undressing barracks were still in existence in early 1944, and that their occasional use for killing Jews deported to Auschwitz as late as the second half of 1943 cannot be ruled out."* (p. 146)

Here the authors are forced to overturn one of the tenets of the fantastic orthodox story of the "bunkers" at Birkenau, according to which, as I pointed out in my comments to Document 16, "Bunker 1" was demolished and the alleged undressing barracks were removed in March/April 1943. The historians at the Auschwitz Museum arrived at this tenet based on testimonies, starting with the fundamental one by Szlama Dragon. If they want to change that story line now, they will also have to admit that the testimonies upon which the old version is based are incorrect, unreliable or deceitful. But since the entire story of the "bunkers" as extermination facilities is based exclusively on testimonies, that entire story would thus become incorrect, unreliable or deceitful.

There is also another serious problem. Eyewitnesses of the "bunkers" do not refer to any activities of these alleged extermination facilities for the period from March/April 1943 through May 1944, so that the authors' random conjectures are without any anecdotal support.

The authors' interpretation is not merely unfounded, but also contradictory. In fact, they claim that the "Special Operation 1" mentioned in the file memo of 9 May 1943 (their Document 33) refers to "Bunker 1." In that case, two of the three alleged undressing barracks would have been dismantled already in May 1943 and installed at the "stable farm Birkenau." There can be little doubt about that, because Bischoff had declared that their setup was "particularly urgent," and because Kammler had ordered the transfer of 60 inmate carpenters from Weimar and Neuengamme to Auschwitz for this project.[161] If that is so, how could there still have been three barracks near "Bunker 1" in February 1944?

I will return to this document's reference to the crematoria in Section 12 of Part Two.

[33] Document 35 (pp. 149-151)

Document 35 is a telegram by Kammler to Bischoff dated 21 May 1944 with the following text:

> *"For Special Operation Hungary Program 3 horse-stable barracks are to be set up immediately at the evasion bunkers."*

---

[161] RGVA, 502-1-233, p. 35.

The authors, who erroneously translate the German prefix *Ausweich*- as reserve, assert that this document refers to "bunker II, referred to here as a 'reserve bunker' (*Ausweichbunker*)" (p. 148).

For the real meaning of this document, I point the reader to what I have already laid out in a different study (2004b, pp. 96-98), and I elaborate on it further here.

On 31 May 1944 Bischoff, as head of the Construction Inspection Office of the *Waffen*-SS and Police, Silesia, sent a letter to the Central Construction Office on the subject "Construction of three horse-stable barracks for Special Operation Hungary," in which he advised, with reference to Kammler's telegram of 25 May, that the barracks were to be picked up from Construction Depot I (depot for storing construction material) of the Construction Inspection Office of Silesia, and he requested the immediate preparation of the necessary administrative documents for the construction.[162] This is the authors' Document 37, of which they published a transcript of the original.[163]

Their interpretation is based on a misreading of the two terms *Sonderaktion* (special operation) and *Ausweichbunker* (evasion bunker). As to the first, the authors tacitly assume that it referred to the alleged gassing of Jews. In fact, as I have shown with documents in a dedicated study, the term had a wide range of meanings that not only revolved around the internment of Jewish deportation convoys and the transport and storage of their personal effects, but also referred to the construction of hygienic and sanitation facilities, and in one case even to the interrogation of civilian workers by the Political Department of the camp (2004b, pp. 60-75, 96-99).

The *Sonderaktion* was finally also connected to the collection and sorting of Jewish assets. SS-*Sturmbannführer* Alfred Franke-Gricksch made an inspection visit to Poland between 4 and 16 May 1943, about which he wrote a detailed report. Among other things, he visited Auschwitz and Lublin, where he became interested in *Operation Reinhardt*. Today, only an English translation of this report is known. It uses the term "'special enterprise' Reinhard,"[164] while another translation of the document shows the original expression: "*Sonderaktion* 'Reinhard,'" which is described as follows:[165]

> *"This branch has had the task of realising all mobile Jewish property in the Gouvernement Poland."*

This explains the request dated 24 December 1943 from the head of the Central Construction Office to the SS Garrison Administration:[166]

---

[162] Letter by the Leiter der Bauinspektion der Waffen-SS und Polizei "Schlesien" (Bischoff) to the Central Construction Office of 31 May 1944. RGVA, 502-1-251, p. 46.

[163] RGVA, 501-2-351, p. 46.

[164] TNA, WO 309-374, pp. 6f.

[165] TNA, WO 309-2241, p. 6.

[166] Letter by the head of the Zentralbauleitung to the SS Standortverwaltung of 24 December 1943. RGVA, 502-1-345, p. 69. See Mattogno 2004b, Document 23, p. 136.

> *"For the operations of the Construction Office of the POW camp Birkenau, the following drafting instruments are most urgently required:*
> *10 sets of drawing instruments, 10 stylographs*
> *10 slide rules*
> *5 calipers*
> *It is requested that these be made available on loan to the Construction Office from the stores of the special operations."*

A message partially deciphered by the British on 18 Dec. 1942 spoke of "stocks from the Jewish resettlement" which included watches and razors, among other things.[167]

This also explains the "special operation" mentioned in Document 33.

Next we turn to the authors' faulty interpretation of the term *Ausweichbunker*. First, the authors' translation for *Ausweich-* as "reserve" is flawed. The German verb *ausweichen* translates as "to get out of the way of something, to avoid, elude, evade, dodge, swerve, shirk, duck." The term "reserve" is nowhere connected to it. It can therefore not surprise that this structure had nothing to do with the alleged "Bunker 2." This is already clear from the fact that "Bunker 2" is said to have been the only homicidal "bunker" in operation in the summer of 1944, while the three barracks for the "Special Operation Hungary" had to be installed "at the reserve bunker**s**" ("*bei de**n** Ausweichbunker**n***") in the plural.

Ausweichbunker were in fact harmless bomb shelters – built so people could "get out of the way of, avoid, elude, evade, dodge, swerve, shirk, duck" Allied bombs. Point 2 of Garrison Order No. 12/44 of 12 April 1944, titled "evasion points in case of air-raid alarm" (*Ausweichstellen bei Fliegeralarm*), provided that, in case of an air-raid attack against housing, the rank and file should seek shelter in the indicated "evasion rooms" (*Ausweichräume*) and explained:[168]

> *"The evasion rooms are meant to have the purpose of protecting rank and file from bomb blasts, shrapnel, and fire"*

The various types of air-raid shelters also included proper air-raid shelters (*Luftschutz-Bunker*), which were bomb-proof structures (*bombensichere Bauwerke*).[169] Therefore the "evasion bunkers" (*Ausweichbunker*) were air-raid bunkers probably destined for the SS troops running the camp.

Garrison Order no. 13/44 of 2 May 1944 dedicated its Point 6 to the "pollution of the line of bunkers," complaining that:[170]

[169] SS-Wirtschafts-Verwaltungshauptamt. Amtsgruppe C. Amt C II - Technische Fachgebiete. "Richtlinie Nr. 58" of 14 July 1944. RGVA, 501-1-401, page number illegible.
[170] Frei *et al.* 2000, p. 442.

> *"The prisoners use the prepared field positions and bunkers within the large sentry cordon as toilets."*

Regarding other documents, the authors write:

> *"Two more telegrams with similar contents were sent to Auschwitz several days later, on May 25 and 30, 1944."* (p. 148)

In reality only one document exists, the original of which, dated 25 May 1944, was published years ago by me (2004b, Document 25, p. 138).[171] The authors reproduce it on p. 150. The transcript of this telegram reproduced on their p. 149 bears the erroneous date of 21 May;[172] this document was again transcribed on 30 May (reproduced on their p. 151); yet another transcript which the authors did not publish was passed on to Jothann at the Birkenau Construction Office on that same day.[173]

In conclusion, the three horse-stable barracks for the Special Operation Hungary had to be set up near air-raid shelters and had consequently no relation to the imaginary "Bunker 2."

[34] Documents 36 (pp. 153-156), 40 (p. 167) and 42 (p. 171)

Document 36 is presented by the authors as follows:

> *"Request dated May 26, 1944 for the re-erection of three barracks designated for a special operation (*Errichtung von 3 Baracken für Sondermassnahmen*). There can be no doubt that they were to be located at one of the already existing bunkers, which previously bore the number II. Page 2 of this document is a standard formula used to describe the implementation of construction projects. The rubric 'time of construction' (*Bauzeit*) often refers in such documents not to any specific step, but rather to the general time frame of the entire construction project. That is why the protocol contains the information that the work on erecting the barracks in Birkenau for special operations was begun in March 1942 (*Bauzeit: mit den Arbeiten wurde im März 1942 begonnen*). This is indirect evidence that bunker I dates from and began operating in March 1942."* (p. 152)

The document in question is a "construction request for the expansion of the PoW camp of the *Waffen*-SS at Auschwitz Upper Silesia. Installation of 3 barracks for special measures" prepared on 26 May 1944.[174] The authors' claim that this was a re-erection is only a transparent ploy to create a fictitious connection with the alleged barracks of "Bunker 2" of the first operational phase (mid-1942 to early 1943). Their claim about the "indirect proof" of the existence of "Bunker 1" since March 1942 is absolutely inconsistent. The reference

to the beginning of the work in March 1942 is in fact a standard phrase taken from another application form, like the one directly thereafter: "The buildings have [been] completed and handed over for use to the SS garrison administration," which, if it were true, would mean that Jothann filed a construction request *after* the structure had already been finished and handed over!

The authors, however, commit an even more serious error – attested to by their comment on Document 42 – attributing to the elusive "Bunker 2" both the "3 horse-stable barracks for Special Operation Hungary" and the "3 barracks for special measures," as if they were of the same barracks. In reality, however, as is confirmed by their Document 42, these were two different structures: the "3 barracks for special measures" were part of *BW* 54, while the "3 horse-stable barracks for Special Operation Hungary" were part of *BW* 33a.

Document 42 is a "list of existing construction requests of the Central Construction Office for the construction project PoW Camp Auschwitz, Upper Silesia." The first three columns show the serial number, the structure's ID, and the number and date of construction order. Entries no. 49 and 50 have the following handwritten annotations:

> *"49. 33A 3 barracks for special measures*
> *50. 54 3 barracks for special measures (Hungary)."*

The authors comment:

> *"The meaning of this entry is not completely understood. It might, however, be hypothesized that two orders have been entered twice, and that the annotation (*Ungarn*) in point 50 actually pertains to point 49 because the designation of investment BW33A corresponds to work connected with the undressing barracks that existed at the bunkers in 1942 and 1943."* (p. 170)

It is clear that they have understood nothing of the issue at hand, particularly when considering their false interpretation of the explanatory report of 30 September 1943 (their Document 17). They interpret the document in retrospect, as if (in this case) it were referring to barracks already completed in the past. Only by doing this are they able to allocate the three barracks for special measures Type 260/9 mentioned therein for Construction Sectors II and III of Birkenau to the "bunkers," which are said to have gone into operation in 1942.

In reality, however, this is a very simple project, as is clear from the fact that three barracks of Construction Sector III, called *BW* 33a, are preceded by a series of structures related to the hospital camp (*BW* 3a, 4c, 4e, 4f 6 c , 7 c, 12 c, 12 b), a total of 167 barracks, but on 6 October 1943, about a week after the preparation of the explanatory report mentioned above, the shells of only 47 barracks had been erected (*im Rohbau*).[175] As I explained above, both the

[175] Letter by Jothann to Kammler of 6 October 1943. RGVA, 502-1-351, p. 352.

existing houses as well as the barracks for special measures appear for the first time in this document, which means that the barracks did not exist prior to 20 September 1943.

Another essential thing which has escaped the authors' attention is the fact that the three barracks for special measures from the construction request of 26 May 1944 (Document 36) are identical to the three barracks for special measures in Construction Sector III of the explanatory report of 30 September 1943: the planned expenditure is in fact identical (RM 55,758), and Document 42 identifies these three barracks as *BW* 33A (or 33a).

This is further confirmed by a document ignored by the authors. It is the construction expense ledger (*Bauausgabebuch*) of *BW* 54, headed precisely "3 barracks for special measures."[176] It gives the expense chapter with "21/7 b" and the title "(*Bau*) 65". The back specifies the work carried out on 5 September 1944 by the company Lenz & Co. A.G. Kattowitz for a total amount of 681.08 RM. It can therefore be stated with certainty that the three barracks in question were erected in early September 1944.

The "Construction Order No. 61" issued by Bischoff as head of the Construction Inspectorate of the *Waffen*-SS and Police "Silesia" dated 11 July 1944 is about the "construction request for the installation of 3 barracks for special measures." The reference is to a letter from the Central Construction Office dated 19 June with registration number 51851/44/Tei/L. The total expense is calculated as 51,000 RM.[177] The authors' Document 40 (p. 167) allows us to correctly interpret Bischoff's order.

On 19 June 1944, Jothann sent to the Construction Inspectorate of the *Waffen*-SS and Police "Silesia" a letter with protocol number 51851/44/Tei/L. with the subject: "CC II – Structure: – Construction Request for installation of 3 barracks for special measures in CC II [Birkenau]." Attached to this letter was the construction request of 26 May 1944, which in fact bears the stamp "*Geprüft*" (audited) of Construction Inspectorate of the *Waffen*-SS and Police "Silesia" with the date of 6 July 1944. The estimated cost was 61,000 RM, recorded in expenditure item 21/7b (*Bau*) 65, which was that of structure *BW* 54.[178] All these data coincide with those of Bischoff's "Construction Order No. 61," except for the expense, which was undoubtedly reduced by his office from 61,000 to 51,000 RM.

It can therefore be concluded with certainty that the "3 barracks for special measures / *BW* 54" had no relation to the legendary "Bunker 2."

The text of Document 36 published by the authors was a first version that was subsequently edited by hand (the total due for the three barracks was reduced from 55,758 to 46,467 RM). The document is partially torn at the mar-

gin. I reproduce all pages of the final, edited version in the Appendix (my DOCUMENT 22).

[35] Document 37 (p. 159)

As mentioned before when discussing Document 35, Bischoff sent a letter to the Central Construction Office on 31 May 1944 with the subject "Construction of 3 horse-stable barracks for Special Operation 'Hungary.'" With reference to Kammler's order of 25 May, he stated that the barracks had to be taken from *Bauhof* I (storage of construction materials) of the Construction Inspectorate "Silesia," and demanded that the administrative steps needed for this construction be carried out instantly.[162] This is the authors' Document 37, of which they published merely a transcript of the original.[179] They comment as follows:

> *"These barracks had not yet been built, but they were at the so-called Bauhof I—the construction material depot near the Auschwitz main camp (*Die Baracken sind dem Bauhof I der Bauinspektion 'Schlesien' zu entnehmen*). In the first phase of the extermination of the Jews deported from Hungary, the persons destined to die in bunker II were made to disrobe in the open air nearby. This is confirmed by an aerial photograph of the Birkenau camp taken by an RAF aircraft on May 30, 1944, in which only the vestigial outlines of the old undressing barracks are visible."* (p. 158)

On p. 159, below this document, the authors publish a section of an air photo showing the area of the alleged "Bunker 2." Here they commit yet another blunder, because the air photo in question was taken on 31 May 1944 by an aircraft of the U.S. Air Forces.[180] I have dealt in depth with this and other air photos in two of my earlier studies.[181]

The issue is much more complex than the authors would have you believe. It concerns not only three barracks, but also the activities around the alleged homicidal "Bunker 2."

In the photo of 31 May 1944, the old "forest road," which is discussed here in the section dealing with Document 19, is no longer well defined; the disused road seems to have been invaded by vegetation. This is in contrast to the three rectangular shapes which show newly cleared areas. It is therefore impossible that these were the footprints of the barracks that had been dismantled more than a year before.

Two barracks, erected on two of the three rectangular shapes just mentioned, appear in the vicinity of "Bunker 2" for the first time in an air photo

---

[179] RGVA, 501-1-351, p. 46.
[180] NA, Mission 60 PRS/462 60 SQ, Exposure 3056.
[181] Mattogno 2004a, pp. 226f.; Mattogno 2005c, pp. 101-103 (photo of 31 May 1944 and its section enlargements).

taken on 26 June 1944,[182] and more-clearly still on a photo made by the Royal Air Force on 23 August 1944.[183]

On this photo, the "forest road" appears to have been restored. This road started at the camp's western gate (near the *Effektenlager*), then passed between the two newly erected barracks, and a few meters beyond that it merged into the old road, forming the hypotenuse of a right triangle.

On 30 August 1944, two members of the camp resistance movement, "Stakło" (Stanisław Kłodziński) and an unidentified "J.," sent the following secret message out of the camp:[184]

> *"The gassing of Jews continues. Transports from Lodz, the Netherlands and Italy. The pits in which they cremated the corpses of the gassed at Birkenau when the crematoria were insufficient, are currently filled up* [*obecnie zasypują*] *to erase the traces."*

This means that the outdoor cremations of allegedly gassed corpses had ceased at that time, and consequently that the activities of "Bunker 2" had ceased as well.

However, the two barracks still appear on an air photo taken on 29 November 1944,[185] which also shows the building said to have been "Bunker 2." According to normal practice prevailing in Auschwitz because of the shortage of barracks, when a barrack was no longer needed, it was dismantled and reassembled wherever needed for another purpose. But if the two barracks had been the changing rooms for the alleged victims of "Bunker 2," why were they left in place for three months after the cessation of its activities? This is all the more inexplicable since, according to Czech, the presumed order to "end all homicidal gassings" arrived at Auschwitz on 2 November 1944 (Czech 1990, p. 743).

No known document mentions these two barracks, so it is hard to say what their purpose was. Even though they cannot be the "three horse-stable barracks for Special Operation 'Hungary,'" since those were three barracks rather than just two, it seems certain that they have a direct relation to the deportation of the Hungarian Jews.

The Hungarian Jews were deported between mid-May and early July 1944. They brought to Birkenau enormous quantities of personal items, which were piled up in front of the barracks of the *Effektenlager*, as shown by various era photos (Freyer/Pressac, photos 121-125, pp. 150-155). It is likely that the two barracks in question, erected not far from the *Effektenlager*, were intended to accommodate these items, which had to be protected from the elements. The

[183] Mattogno 2005c, Documents 36 & 37, pp. 117f.
[184] APMO, D-RO/85, vol. II, p. 126.
[185] NA, Record Group no. 373, Mission: 15 SG/887 5 PG. Can: D 1610. Exposure: 4058. *Auschwitz: Open Air Incinerations*, op. cit., Document 41 on p. 122.

expansion of the courtyard of "Bunker 2" can be explained as follows: it was used to unload the material, which was then sorted by the inmates and placed inside the two barracks.

According to "eyewitnesses," the following numbers of cremation pits are said to have operated in the summer of 1944 in the area of "Bunker 2":

– one according to Shaul Chasan and Shlomo Venezia;
– two according to Miklos Nyiszli and Dov Paisikovic;
– four according to Filip Müller.[186]

According to Filip Müller, the preparations for the extermination of the Hungarian Jews in "Bunker 2" (which he called "Bunker V") began in early May 1944. Four "cremation pits" were excavated measuring 40-50 m × 8 m × 2 m. In mid-May the first transports of Hungarian Jews arrived, who were allegedly exterminated in "Bunker V."[187]

Dov Paisikovic claimed to have worked at "Bunker 2" for two weeks, from 23 May to 6 June. According to him, an uninterrupted extermination activity, day and night, unfolded in that area on 31 May 1944. The two mass cremation pits claimed by him measuring 30 m × 10 m or 30 m × 6 m had to operate at full capacity. Pressac spoke of two small pits of 30 and 20 square meters.[188] The orthodox Holocaust writer Mark van Alstine claims to have identified on air photos three "cremation pits" with an area of about 106.8 m² each and about 320 m² in total in the area of the alleged "Bunker 2."[189] Piper did not mention the number of "cremation pits" near "Bunker 2," but claimed that their total capacity was 5,000 corpses per day.[190]

On 31 May 1944, the area of "Bunker 2" would therefore have been an inferno of fire and smoke, but the above-mentioned air photos, including the one published by the authors, show no trace of either smoking or non-smoking pits; or of any kind of smoke; or of any activity of the 100 or 150 inmates who were allegedly employed there; or of trucks delivering fuel wood or removing ashes; or of stacks of wood piled up for the cremation of the corpses. As I mentioned above, in the air photo of 31 May 1944, the "forest road" was not even in use. The only road linking the Birkenau Camp to "Bunker 2" started from the area of the sewage-treatment plant, continued to the southwest, then bent at a 90° angle to the southeast toward the area of "Bunker 2," but it was blocked by a thick hedge preventing access to the fenced-in yard of the building.[191] So the claimed trucks with the victims (which are not visible on any air photo either) had to stop at the end of the road, the victims had to get off the trucks and somehow get through the hedge in order to get to the yard of the al-

[186] Mattogno 2005c, p. 23.

leged "bunker," with the risk of them escaping and having to be shot at, and all this in plain view of the camp. Hence the very air photo presented by the authors radically debunks all their conjectures on the gassing "bunker" and its alleged undressing barracks.

[36] Document 38 (p. 161)

This is a letter by Jothann dated 1 June 1944 with the subject "Erection of 3 horse-stable barracks – Special Operation 'Hungary.'" The authors adduce it as such without any comment.

[37] Document 39 (p. 163-165)

This is a file memo about the Auschwitz visit by SS-*Obergruppenführer* Pohl on 16 June 1944, dated 17 June. In this regard the authors write:

> *"On page 2 of the protocol there is a list of intended construction projects that cannot be carried out until the appropriate proposals have been submitted. Item 10 mentions three barracks needed as urgent measures for the 'Jewish operation' (*3 Baracken für Sofortmassnahme 'Judenaktion'*)."* (p. 162)

This document[192] states that Pohl had authorized the list of 29 requested construction projects, including these three barracks, after he had checked their degree of urgency. Among these construction projects were finishing a building for the Hygienic Institute (Point 2), extending and finishing House No. 7 (Point 11), an air-raid shelter (*Luftschutzbunker*) and a shrapnel-protection shelter (*Splitterschutzbunker*; Points 20, 21 and 29).

The term *Sofortmassnahme* (immediate measures) had no criminal connotation, on the contrary: it is in fact referring to sanitation. For example, on 7 June 1943 the garrison surgeon submitted a request to the Central Construction Office requesting that, "in the course of the immediate measures to improve the hygienic conditions in CC Auschwitz," the hot-air-disinfestation chambers be modified in such a way that they no longer pose any fire hazard.[193] In another letter dated 20 July 1943 with the subject "hygienic immediate measures," Wirths asked the Central Construction Office to install adequate morgues, because rats were feeding on the corpses in the existing wooden ones.[194]

It is also worth mentioning that the term special measures had the same meaning. The entire Birkenau hospital sector *BA* III was a "special measure," as the "List of barracks necessary for the implementation of the special measure in the PoW camp" of 11 June 1943 shows.[195]

---

[192] NO-2359.
[193] RGVA, 502-1-170, p. 150.
[194] RGVA, 502-1-170, p. 263.
[195] RGVA, 502-1-79, p. 100. See Mattogno 2016c, Document 26, p. 334.

[38] Document 41 (p. 169)

This is the well-known "Construction Order No. 63," signed by Bischoff on 20 July 1944, which refers to the "construction request for the erection of 3 barracks for special measures," for a total amount RM 41,000.[196] The authors comment on this as follows:

> *"Under point 13 on page 2 of document 7 above, there is information that three barracks for the 'Jewish operation' (*Judenaktion*) are 90 percent completed. RAF aerial photographs from the second half of August 1944, however, show that in the end only two undressing barracks were built at bunker II."* (p. 168)

The reference to their Document 7 is to the "List of structures under construction with extent of completion" dated 4 September 1944, which in Paragraph 13 of the list b) reads: "3 barracks for immediate measures (Jewish operation)." The list also includes finishing a residential house for agriculture (List a), Item 9), finishing two residential houses for civilian employees (Item 20), temporarily finishing 60 residential houses in the relevant camp area for bombed-out SS members (Item 43), finishing a house for the Hygienic Institute (List b), Item 5), and the extension of House No. 7 (Item 14). The authors do not even ask why the documents supposedly list the erection of the undressing barracks at the elusive "bunker," while being absolutely silent about the transformation work which would have been required to convert the two relevant existing houses into the claimed gassing facilities, although documents on similar conversion projects appear in abundance for many existing houses which the Central Construction Office had taken over and put to one use or another.

The authors' conjecture is also senseless from a chronological point of view. Kammler's telegram containing the order to erect three barracks for "Special Operation Hungary" dates back to 25 May 1944. The deportation of Hungarian Jews to Auschwitz began on 15 May 1944, and the first transport arrived at the camp on May 17 (Czech 1990, p. 628). By 25 May, already 138,870 Jews had been deported in 44 trains.[197] During these first 10 days, on average almost 13,900 Jews arrived at Birkenau every day, most of whom, according to the historians at the Auschwitz Museum, were gassed in the claimed extermination facilities at Birkenau, including "Bunker 2." If, therefore, Kammler's order was referring to the erection of three undressing barracks near "Bunker 2," this was not only a little late (the deportation schedule had been discussed in Vienna on 4 and 5 May 1944,[198] at which point Auschwitz camp administration must have been informed about the upcoming deportations). In addition, the order was not even implemented!

---

[196] RGVA, 502-1-281, p. 57. See DOCUMENT 23
[197] NG-5623.
[198] NG-5565.

Fact is that the deportation of the Hungarian Jews ended on 8 July 1944, and the last transport arrived at Auschwitz three days later, but on 4 September the three barracks in question had still not been finalized and were not yet in operation. Even if they were for the "Special Operation 'Hungary,'" the barracks now were meant to serve a completely different purpose. In fact, the "Hungary Program" brings to mind the "fighter-construction program," a program for the construction of underground aircraft factories to quickly build a large fleet of small aircraft capable of defending Germany against the Allied bomber fleets. For this purpose, Hitler informed Luftwaffe Field Marshal Erhard Milch on 9 April 1944 that Himmler was in charge of gathering 100,000 Hungarian Jews for this program,[199] and on 9 May the Führer ordered the withdrawal from Sevastopol of 10,000 men to watch over 200,000 Jews who were about to be sent to concentration camps in order to be deployed in that program.[200] Kammler's stake in the "Special Operation 'Hungary'" program was that he was Himmler's representative in the German government department overseeing the production of fighter aircraft; he was the "Plenipotentiary of the *Reichsführer*-SS at the Reich Ministry for Armaments and War Production, 'Fighter Staff'" (*Bevollmächtigter des Reichsführers-SS beim Reichsmininisterium für Rüstung und Kriegsproduktion, 'Jägerstab'*).[201]

IV. Section "The Railroad Ramp (*Alte Judenrampe*)"

This section is the most-tenuous of the whole book, since the documents proffered have not the slightest relevance to the alleged extermination of the Jews.

[39] Document 43 (p. 175)

This is a file memo by SS-*Untersturmführer* Kirschnek dated 28 July 1943 which merely mentions the "Jews ramp" (*Judenrampe*), and this is the only reason why the authors published it, as if this fact had been unknown! They explain that on this ramp "SS men received transports of deportees and subjected them to selection from mid-1942" (p. 174). Is the presence of the railway ramp supposed to be evidence for the claim that arriving Jews were gassed later on?

[40] Document 44 (p. 175)

It is a sketch by the industrial construction company Schlesische Industriebau Lenz & Co. AG on a project called "railway construction – potato transportation to the potato bunker" – another real yet innocuous bunker! The sketch sports a label saying "external ramp – Jew track" – and that's all!

---

[199] R-134.
[200] NO-5689.
[201] NARA, T 175/226, 2764970.

[41] Document 45 (p. 179)

This is a letter by Bischoff to Kammler of 19 January 1943 concerning the construction of a spur from the Auschwitz railway station to the Birkenau Camp. The authors comment:

> *"The first of its functions mentioned here is receiving transports sent to the camp within the framework of special operations (*Direkte Anfahrt der Transportzüge – Sondermassnahmen*)."* (p. 178)

The German phrase translates to: "Direct approach of the transport trains – special measures." But what proves that these "special measures" were homicidal gassings? Above I have elaborated on the various meanings of the terms *Sondermassnahme* or *Sofortmassnahme*, so there is no need to probe the subject here again.

[42] Document 46 (pp. 181-183)

This is a report on a meeting of 23 March 1943 between representatives of the railway management at Oppeln (today Opole) as well as members of the Auschwitz Central Construction Office and camp headquarters. The report is dated 25 March 1943. Among the issues discussed is also that of a railway spur between the Auschwitz railway station and the Birkenau Camp. The authors point out:

> *"The report includes information about plans to use the freight station as the place for the 'unloading of special transports of the office of the commandant of Auschwitz concentration camp' as well as for the unloading of construction materials required by the Zentralbauleitung. Additionally, the document mentions the necessity of expanding the area of the freight station so that it can handle the daily arrival of 10 special transports and 40 train cars carrying construction material and supplies (*Soll das Baugleis täglich neben dem Baustoffverkehr mit bis zu 10 Sondertransporten und bis zu 40 Waggons mit Baustoff, Verpflegung usw. für die Kommandantur und die Zentralbauleitung belastet werden*)."* (p. 180)

Apparently, the authors reproduced this document merely because it contains the term "special transports," which for them is obviously evidence that the majority of these "special transports" were then gassed.

[43] Document 47 (pp. 185)

This is a letter by the German State Railway (*Reichsbahn*) to the Central Construction Office dated 17 March 1943. It refers to "Relocating the ramp for the camp's special transports." Here, too, the magical term "special transports" appears.

[44] Document 48 (pp. 187)

This is page 335 of the inmate labor-deployment register (see their Document 12) which confirms the "Relocation of the ramp for special transports," and that is all.

Since the authors seem to be obsessed with the "relocation of the ramp for special transports," I inform them that more documents exist in this regard, the "File memo about a conference with representatives of the *Reichsbahn* at the Central Construction Office of the *Waffen*-SS and Police Auschwitz on 9 April 1943 regarding relocating the ramp for special transports,"[202] and a "Report on the relocation of the ramp for special transports."[203]

[45] Document 49 (pp. 189-191)

These are two documents, a letter from the *Reichsbahn* railway management Oppeln to the Central Construction Office of 20 April 1943, and a letter from the Central Construction Office to the camp commandant of 25 March 1943. In both the magical term "special transports" appears again, and that's good enough for the authors to include it. What they imagine this proves remains a mystery.

[46] Document 50 (p. 193)

This document is about the "potato-storage warehouses." The authors explain:

> *"They were built in 1943 near the unloading ramp where Jewish transports were received in the period from the spring of 1942 to May 1944 and subjected to selection. The location and dimensions of the unloading ramp are visible, as is the road running in the direction of the Birkenau camp that was defined as the 'camp access road' (*Zufahrtstrasse zum KGL*)."* (p. 192)

In this document, not even the term "special transports" appears but simply the word "ramps"!

They could just as well have reproduced the map of 21 June 1944 showing the area between Sectors I and II of Birkenau which Pressac published decades ago and which even indicates the width of the two ramps: 2 and 10 meters, respectively ("*Rampe 2 m breit; Rampe 10 m breit*"; Pressac 1989, pp. 254f.).

[47] Document 51 (pp. 195f.)

This is a file memo by Bischoff of 12 July 1943 mentioning the "track for special transports" (*Gleis für Sondertransporte*). Yet another irrelevant document.

---

[202] RGVA, 502-1-186, pp. 205f.
[203] RGVA, 502-1-86, pp. 160f.

V. Section "The *Sonderkommando*"

[48] Document 52 (p. 201)

This is a compilation of expenses for materials at the Birkenau Camp. On 23 April 1942 are recorded 300 kg of cement and 400 kg of bagged lime (*Sackkalk*; see my DOCUMENT 28). The authors explain that these materials had been "required by the *Sonderkommando*" and that the lime "was used as a disinfectant when burying bodies in mass graves" (p. 200).

This is a deliberate misrepresentation for two reasons. First, *Sackkalk* was a German term for powdered unslaked lime (CaO) sold in bags to the pottery and construction industry (see Lamock 1911). It was and is to this day one of the major components of mortar and plaster, together with cement, water and sand. The fact that the lime was listed together with cement should alert readers to the incontrovertible fact that here simple building materials were ordered. But the authors very prudently decided to ignore the cement so that they wouldn't have to repeat the absurd explanation in their introduction.[204] After all, what was the alleged *Sonderkommando* at the elusive "bunkers" supposed to have done with 300 kg of cement? Besides, had the SS ordered lime-based powder for disinfection purposes, they would have ordered chlorinated lime (*Chlorkalk*),[205] see the next document discussed.

Next, the authors pass over a second central bit of information: the complete recipient of these supplies: "*BW*. 4 Sonderk. Bir.," which means "Structure 4 of the Birkenau *Sonderkommando*." *BW* 4 Birkenau referred to the construction of 14 barracks for economy (*Wirtschaftsbaracken*).[206] The construction work of two of these barracks, labelled *BW* 4a, had started on 10 November 1941; one had been completed at the end of March 1942, the second was 90% finished, and its completion was scheduled for 31 May 1942.[207] The above-mentioned construction materials were used for building these very barracks for logistical maintenance, and the "Birkenau *Sonderkommando*" was working in it.

[49] Document 53 (p. 203)

This is a request (*Anforderung*) by the "*Sonderkommando* Birkenau" from 10 February 1943 regarding "1 barrel of chlorinated lime." The authors affirm

---

[204] See my comments below on their Introduction, Part Two, Section 11. "Sonderkommando" and "Bunker."

[205] A mixture of highly corrosive calcium hypochlorite $Ca(ClO)_2$, calcium chloride $CaCl_2$ and calcium hydroxide $Ca(OH)_2$.

[206] "BW 4 Wirtschaftsbaracken 1-14"; "Erläuterungsbericht zum Vorentwurf für den Neubau des Kriegsgefangenenlagers der Waffen-SS Auschwitz O/S.," 30 October 1941. RGVA, 502-1-233, p. 14 (p. 2 of the report). It is not entirely clear what a *Wirtschaftbarracke* was, but it may have referred to buildings for activities of logistical maintenance/domestic economy (*Hauswirtschaftbaracke*), like bakery, kitchen, laundry etc.

[207] "Baufristenplan" of the "Kriegsgefangenenlager" dated 5 May 1942. RGVA, 502-1-22, p. 15.

that the *Sonderkommando* used these 200 kg of chlorinated lime "for disinfection" (p. 202), always insinuating that it was meant to be used in mass graves of gassing victims. This is, of course, purely conjectural, because no one knows to which *Sonderkommando* the document refers. But even if it were true that it was used in mass graves, that doesn't prove that a mass murder was going on in Birkenau at that time. Since at that point in time a typhus epidemic had been raging inside the camp for seven months, claiming tens of thousands of victims without adequate cremation capacity, a huge need for chlorinated lime cannot surprise. Actually, it is a miracle that this is the only order for chlorinated lime the museum could locate. But we don't even know whether that lime was meant to disinfect corpses, because that is not the only possible application for chlorinated lime. It is also used in garbage dumps, septic tanks, cesspits, and last but not least for cleaning toilets and other sanitary facilities.

[50] Document 54 (p. 205)

This is Receipt No. 2102 of 18 December 1942 for "*Sonderkommando Nr. 2*" concerning the delivery of 3 tons of coke. Here the authors' incredible interpretation:

> *"In the winter, coke was burned in portable iron baskets to heat the gas chambers."* (p. 204)

This is a ridiculous stopgap trick designed to somehow explain the supply of coke, a hypothesis not backed up by anything, not even an anecdote. Szlama Dragon, who claims to have been assigned to the *Sonderkommando* on 10 December 1942 – eight days before the aforementioned coke delivery – described with great wealth of detail the alleged gassing procedure, but without ever mentioning portable coal baskets (so-called braziers), which in fact wouldn't have been needed, because when the "gas chamber" was opened, it "was very warm" (*było bardzo gorąco*).[208]

Setkiewicz published another document elsewhere which is said to indicate the supply of another 3 tons of coke to this *Sonderkommando* on 26 February 1943. This is not, however, a proper document such as Document 54, but a mere sheet of paper in which the following text appears in handwriting:

> *"3 – –*
> *Sondern* [sic] *Kommando II*
> *26/ Februar."*

It is therefore neither specified whether it is 3 tons of coke nor that the year is 1943. Here is Setkiewicz's incredible comment (2011a, p. 106):

---

[208] Interrogation of Sz. Dragon by investigating Judge Jan Sehn, 10 & 11 May 1945. Höss Trial, vol. 11, pp.103-106.

> *"This suggests that at the time a 'Sonderkommando I' had to exist; in other words, there were two Sonderkommandos assigned to the gas chambers of the 'red house' and the 'white house'."*

A delirious logic, to say the least!

[51] Document 55 (p. 207)

This is a page of the inmate-labor-deployment register from which the authors drew their Documents 12 and 48 (see there). In an entry dated 19 January 1943, we read in the "contents" column:

> *"Request for 2 guards for* Sonderkommando*."*

As in the case of Document 12, the authors fail to report that in the fourth column headed "by whom," giving the entity which filed the request, has the following text: "Administration of Inmate Property." So this *Sonderkommando*, exactly like the one mentioned in Document 12, was sorting and disinfesting inmate belongings. The Administration of Inmate Belongings was a subsection of "Department IV – Administration" of the Auschwitz Concentration Camp.

[52] Document 56 (p. 209)

This is again taken from the just-mentioned register, page 259. On 10 February 1943 a "Request for dentists to the special operation" was filed by the "dental center." The authors merely repeat this request without making any comment. They probably imply that any reader sufficiently imbued with orthodox propaganda assumes that the two dentists in question had the task of extracting gold teeth from the corpses of allegedly gassed victims. This presumably derives from the mere presence of the term "special operation." But the term referred very generally to the arrival of "special transports" with all the operations resulting from it: reception, disinfestation and sorting of the deportees, as I explained earlier. These operations were also called "special measures," as is sensationally confirmed by Document 67, to be discussed further below.

The former detainee Männe Kratz claimed during the hearing on 21 December 1964 of the Frankfurt Auschwitz Trial that he had been part of the dental center's *Sonderkommando*, which he described as follows:[209]

> *"The '*Sonderkommando*' of the dental station was occupied with smelting the gold teeth extracted from the dead."*

The use of the term "special operation" to describe the extraction of gold teeth from dead bodies is not attested to by any document. It is however known that, according to investigating judge Jan Sehn, during 200 days of the year

[209] Fritz Bauer Institut *et al.* 2005, p. 27049.

1942, 16,325 gold fillings or fillings of other precious metal alloys were extracted from the teeth of 2,904 corpses.[210] For this existed special pre-printed forms which read as follows:[211]

> *"Inmate Dental Center of CC Auschwitz. Auschwitz, the ....194...*
> *To the Political Department of CC Auschwitz.*
> *From the corpse of … inmate no. … the following dentures were removed:*
> *1.) precious metal alloy R… L… 2.) Gold R ... L…*
> *Number of links*
> *Total number of links*
> *The Head of the Inmate Dental Center of the CC Auschwitz*
> *SS*-Untersturmführer.*"*

All this happened in broad daylight without any "code word." Removing dentures and dental fillings from corpses prior to their cremation is not only standard practice in every crematorium of the world, but it is also necessary to prevent those metals from accumulating in the cremation device – and from polluting the environment (in case of amalgam fillings).[212] The issue is not that fillings were extracted, but what happened with the precious ones afterwards.

On 14 January 1943 the British decoded the following message sent by the SS-*Führungshauptamt* to the doctor of an unspecified division:[213]

> *"To div. surgeon.*
> *The 18 dentists and dental technicians drafted to the division for a special operation are to be put in motion immediately, together with the additionally supplied equipment, to the SS medical replacement battalion STETTIN, Kückenmühle."*

This suggests that a "special operation" performed by dentists did not necessarily have a criminal character.

[53] Documents 57 and 58 (p. 211-213)

Document 57 is a letter by SS-*Untersturmführer* Josef Janisch to the camp headquarters dated 24 December 1943 with the subject "Return of field railway material made available to *Sonderkommando* I on a loan basis." It states:[214]

---

[210] Höss Trial, vol. 3, p. 86; note that this would amount to 5.6 gold fillings per corpse, which seems a little high.

[211] J. Sehn, "Obóz koncentracyjny i zagłady Oświęcim", in: *Biuletyn Głównej Komisji Badania Zbrodni Niemieckich w Polsce*, I, Poznań, 1946, photo on unnumbered page.

[212] Amalgam is an alloy of silver and mercury. The latter, a poisonous heavy metal, melts and evaporates during cremation.

[213] TNA, HW 16/23, German Decodes No. 3 Traffic: 14.1.43 Addenda to I Traffic. ZIP/GPDD 358a/4.2.43.

[214] RGVA, 502-1-83, p. 54.

> *"A while ago, the Central Construction Office made some field railway material available to* Sonderkommando *I, specifically tracks and wagons. This field railway material, which is currently not being used there, is urgently needed by the PoW Construction Office. It is requested to immediately hand it over to the PoW Construction Office in Birkenau."*

The authors comment on it this way:

> *"It can be concluded from numerous accounts by Sonderkommando prisoners such as Szlama Dragon and Eliezera Eisenschmidt that the transport of corpses from the gas chamber to the burning pits and pyres at bunkers I and II was carried out with the aid of flatcars running on the provisional rails of a field railroad."* (p. 210)

Subsequently the authors present two more documents dealing with the same issue (their Document 58) – a letter by the camp headquarters to the Central Construction Office dated 7 February 1944, and the Office's response on 24 February[215] (p. 213). They highlight the phrase "currently not being used," perhaps because, in their confused version of the orthodox history of the "bunkers," they believe that "Bunker 1" had ceased operations in December 1943. Neither of these documents adds anything new to the debate.

It is true that "Bunker 2" is claimed to have had such a field railway as well. It appears clearly on the map drawn by Ing. Eugeniusz Nosal based on Dragon's instructions (Mattogno 2004a, p. 207, Document 12). Other than that, however, nothing is known about this field railway. Not even the inmate-labor-deployment register, of which the authors publish three pages (their Documents 12, 48 and 55), contains any hint of a field railway loaned to *Sonderkommando I* (supposedly working at "Bunker 1") or to *Sonderkommando* 2 (at "Bunker 2"), because in that case it would have been invariably reported.

Apart from that, the authors' time line of dismantling various items said to have belonged to "Bunker 1" is confused and illogical. Here are some of the things they claim:

- May 1943: request to remove two undressing barracks from "Bunker 1" (their interpretation of Document 33).
- 24 December 1943: request to remove field railway from "Bunker 1" (their interpretation of the present document).
- 4 February 1944: request to remove three undressing barracks from "Bunker 1" (although two had already been removed earlier; their interpretation of Document 34).
- 18 March 1944: request to dismantle an electric wire from "Bunker 1" (their interpretation of Document 20).

[215] RGVA, 502-1-83, p. 41.

If "Bunker 1" ceased its activities in early May 1943, with a large sewage-treatment plant built on its claimed site, why was it noticed only seven months later, on Christmas Eve of 1943, that the field railway was "currently not being used"? Can anyone believe that, after the termination of the alleged activities of "Bunker 1," the railroad would have been left abandoned for seven months, sitting in plain sight of the sewage-treatment plant rusting away?

In the absence of any specific documents, we cannot ascertain the location and purpose of this field railway.

A letter from the company Schlesische Industriebau Lenz & Co. AG to the Central Construction Office of 3 February 1944 contains an offer for a field railway track (*Feldbahngleis*) for "*BW* 47 – *BA* III,"[216] which was to be used to transport construction materials. This shows that the presence of a field railway in Auschwitz was not necessarily linked to any alleged extermination activities.

VI. Section "*Sonderaktionen*" (Special Operations)

[54] Document 59 (p. 217)

This is a letter from Bischoff to the camp Headquarters dated 18 August 1942 with the headline "immediate measure" (*Sofortmaßnahme*). This is the text:

> *"Due to constant labor interruption caused by the special operation, the Central Construction Office requests the allocation, with immediate effect, of one additional NCO and three guards for the labor detail PoW Camp ring trench, Construction Sector III (100 inmates, currently with four guards), so that it can be deployed for urgent excavation works at the Vistula trench with a guard* [ratio] *of 1:6."*

The authors claim that the prisoners of this excavation detail "at the time were used to dig drainage ditches near the bunker I" (p. 216), but they do not explain the document's meaning in this perspective.

First, why does it mention only one "special operation" in the singular rather than "special operations" (= alleged homicidal gassings) in the plural, as would have to be expected? How and why could the "special operation" constantly interrupt this detail's work? How could four additional guards prevent further interruptions? And apart from that, four additional guards would increase the ratio only from 1:25 to 1:12.5, not 1:6, as the document claims.

Without the aid of other documents it is very difficult to determine what the special operation in question was about, but we can assume this document was about the same inmate detail as the one mentioned in Document 66.

---

[216] RGVA, 502-1-346, p. 44.

[55] Document 60 (p. 219)

On 14 September 1942, SS-*Obersturmbannführer* Arthur Liebehenschel, head of Office D/I of the SS-*WVHA* (*Zentralamt*),[217] signed the following travel permit (*Fahrgenehmigung*):

> *"For the purpose of an urgent transfer of 5 trucks and an accompanying machine, a travel permit from Oranienburg to Auschwitz is herewith issued for 14 September 1942.*
> *Reason:*
> *Immediate transfer of the allotted trucks to C.C. Auschwitz, since these vehicles have to be used immediately for special operations."*[218]

This is the content of Document 60, which the authors interpret as follows:

> *"These trucks were used to carry deported Jewish children and those who were too sick or frail to march from the 'old ramp' to the gas chambers. They also delivered the victims' luggage to the 'Kanada 1' warehouses."* (p. 218)

As I explained earlier, in September 1942 the personal belongings of the Jewish deportees were disinfected and stored as part of "Operation Reinhard," and it is evident that those belongings were to be transported from the Auschwitz railway station to "Kanada I" and to "Station 2 of Aktion Reinhard" Birkenau, then into the various warehouses at Auschwitz and Birkenau. That is why the trucks were needed. This is further confirmed by Document 61, while the authors' claim that the trucks served to transport kids and disabled inmates to the "gas chambers" is not in the least supported by any document.

[56] Document 61 (p. 221)

This is a transfer document from Dachau to Auschwitz "for Operation 'Reinhard'" concerning 12 non-commissioned SS officers and soldiers, including the already-mentioned SS-*Hauptscharführer* Georg Höcker and SS-*Unterscharführer* Heinz Kühnemann. As I demonstrated in my comments on Document 31, they were employed in the disinfestation and storage of Jewish belongings. It is not clear why the authors have included this document in the section of "special operations," since it does not contain any reference to this term.

[57] Document 62 (p. 223)

This is a note (*Vermerk*) by Bischoff dated 1 October 1942 saying:

> *"During the service meeting on 28 September 1942 at Camp Commandant* Obersturmbannführer *Höss's, the undersigned, in his capacity as building*

---

[217] Department 3 of the office (D/I/3) was in charge of motor vehicles (*Kraftfahrwesen*).
[218] Trial of the Auschwitz camp garrison, vol. 38, p. 113.

> *inspector, drew attention to the fact that no luggage and refuse from inmate belongings are to be incinerated nearby buildings, since otherwise a conflagration can break out, to which whole parts of the camp could fall victim.*
> *As determined on Saturday, 26 September 1942, the start of a fire could be prevented at the last minute, which was caused by carelessly burning old suitcases and the like at the effect barracks south of the DAW."*

The authors do not provide any explanation, except that "at the time, these items were stored on the grounds of the 'Kanada 1' storehouses located near the Auschwitz I camp." (p. 222)

As with the previous case, it is not clear what relationship this document has with "special operations" in the eyes of the authors. Instead, it illuminates the background of Höss's visit to the "experimental station for field furnaces Operation Reinhard," which had taken place only a few weeks earlier, on 16 September 1942.

In an older study, in which I treated that issue in depth, I demonstrated the utter absurdity of the interpretation proffered by orthodox Holocaust historians (that is, that Höss had gone to Chełmno to learn from Blobel a corpse cremation technique which was then also to be introduced at Auschwitz) and eventually I came to the conclusion that this trip had nothing at all to do with cremating corpses (2008, p. 56):

> *"Even the claim that these 'field furnaces' were intended for corpses is actually a simple hypothesis: in hindsight, in fact, there is nothing in the two documents mentioned above – Dejaco's report and the travel permit by the SS-*WVHA *– indicating that this was about cremating corpses. The 'field furnaces' really had nothing to do with cremation furnaces. The famous engineering manual 'Hütte' describes them as follows:*
> *'Ceramic furnaces (brick furnaces). Combustion temperature from 800 to 1200°. One distinguishes furnaces for temporary operation and furnaces for continuous operation. The first is part of the so-called field furnace, rectangular with solid side walls and stoking channel at the bottom. The furnaces are between 4 and 9 meters wide, as long as needed, and open at the top.'*
> *The device designed by F. Siemens was indeed specifically a 'Feldofen für Leichenverbrennung' (field furnace for cremating corpses).*[219]
> *However, since the 'Operation Reinhard' at Auschwitz simply meant the collection and exploitation of property stolen from the Jews, the term 'field furnaces' could refer in one way or another only to these goods."*

At the time I did not want to get deeper into the matter, but Document 62 provides the missing key: in the Auschwitz Camp, combustible refuse from the

---

[219] I published the design of this device: Mattogno/Deana 2015, vol. II, Doc. 93, p. 130.

deportees' belongings was burned outside, and this was dangerous. Höss therefore travelled to a place near Litzmannstadt (Łódź), not to Chełmno! The authorization for this trip (*Fahrgenehmigung*), coming directly from Glücks as head of Office Group D of the SS-*WVHA*, referred expressly to a trip "from Auschwitz to Litzmannstadt and back,"[220] while Chełmno is located about 60 km north-west of Łódź. On the other hand, Chełmno had no relation to "Operation Reinhard" (or Reinhardt). Furthermore, no orthodox Holocaust historian has yet managed to explain why any experimental corpse cremation for the Reinhardt camps (Belzec, Sobibor, Treblinka) would have been conducted at Chełmno rather than at those camps or at Auschwitz, and why those experiments would have been entrusted to a layman like Blobel, while the engineer supervising the planning and construction of the crematoria at Auschwitz was one of the leading German specialists in that field: Engineer Kurt Prüfer.

The "Travel report service trip to Litzmannstadt," prepared on 17 September 1942 by SS-*Untersturmführer* Walter Dejaco on the trip he had made the day before together with Höss and SS-*Untersturmführer* Franz Hössler – but without Garrison Surgeon Wirths or any of his representatives, which would be strange if this had been about inspecting a cremation device – contains another important element: it was decided to hand over to the Auschwitz Camp a "ball mill for substances."[221] This ball mill was a spinning metal drum with metal balls inside to pulverize the materials placed in it. There is not even a trifle of support for the orthodox hypothesis that this device served to crush the cremated bones of alleged gassing victims. In the context outlined above, however, this device can be understood as the counterpart to the "field furnaces:" the mill was used to grind down the incombustible remains from incinerating the refuse from the deportee's belongings.

[58] Document 63 (p. 225)

On 13 October 1942, Bischoff sent a letter to the head of Office C/V of the SS-*WVHA* with the subject "Assignment of construction tasks for the new construction of the prisoner-of-war camp of the *Waffen*-SS in Auschwitz, Upper Silesia" which states, among other things:[222]

> *"Due to the situation created by the special operations, the construction of the crematorium had to be begun immediately just this past July. The firms of Huta, Hoch- und Tiefbau-A.G., Kattowitz, Friedrichstr. 19, and Schles. Industriebau Lenz & Co, A.G., Kattowitz, Grundmannstr. 23, which are already working in the prisoner-of-war camp, were invited to a restricted bidding.*

[220] AGK, NTN, 94, p. 170.
[221] RGVA, 502-1-336, p. 69.
[222] GARF, 7021-108-32, pp. 45-47.

> *According to a letter of 15 July 1942, the Schles. Industriebau Lenz & Co. made no bid due to lack of workers. For this reason, the Huta firm was commissioned immediately to begin work in accordance with its bid of 13 July 1942."*

This letter, known even to Pressac, was published by the authors as their Document 63 with this following comment:

> *"The 'situation' that Bischoff writes about surely refers to the constantly rising number of people who were deported and killed in the gas chambers."* (p. 224)

In other words, they opine that the construction of the new crematorium was commenced instantly because of the gassings in "Bunkers" 1 and 2. This interpretation is unfounded and contradictory, as I showed in an earlier dedicated study (2004b, pp. 62-66), which I will reiterate here.

The sentence "Due to the situation created by the special operations, the construction of the crematorium had to be begun immediately just this past July" means that the special operations had created an *unexpected* new situation. The limited bidding mentioned by Bischoff was thus the first consequence of these circumstances. Since it took place at the instance of the Central Construction Office on 1 July 1942,[223] the new situation must have manifested itself in all its urgency already before this date.

On the other hand, dealing with this question was not at first a matter of urgency for the Central Construction Office. After the Lenz firm declined to submit an offer on 15 July, they waited fourteen days before concluding a contract with the Huta firm.[224] In July 1942, prisoners under the authority of the Central Construction Office had "finished the excavation work at the crematorium,"[225] which had already begun the previous month.[226] The actual construction work began in August.[227] The PoW camp's construction schedule for July gives the second of that month as the starting date of the construction of the crematorium.[228]

However, the "special operations," in the orthodox sense, allegedly began on 4 July, the date on which, according to Danuta Czech, the "selection" of a Jewish transport took place for the first time at Birkenau, in consequence of which those "selected" were allegedly gassed in the "bunkers" (Czech 1990, pp. 191f.). The necessity to immediately begin the construction of the crema-

[228] "Baufristenplan 1942." "Berichtsmonat Juli" for the PoW camp. RGVA, 502-1-22, p. 32.

torium can, therefore, have had nothing to do with these alleged "special operations."

But there is a much more fundamental problem: Why would the "special operations" have made the construction of the crematorium so urgently necessary, if *no crematoria whatsoever had been planned for "Bunkers" 1 and 2*? Their alleged victims were supposedly just buried in mass graves!

It deserves emphasis that the crematorium of the PoW camp was planned for the cremation of registered prisoners who had died "naturally," but not for criminal purposes, that is, for the cremation of murdered inmates, as Pressac demonstrated impeccably (1994, p. 64).

According to the *Auschwitz Chronicle*, the burning of those allegedly gassed in the "bunkers," together with the dead buried in mass graves, is supposed to have begun on 21 September 1942 (Czech 1990, p. 242), allegedly resulting from an order issued by Himmler on 17 July 1942, on the occasion of his visit to Auschwitz. Franciszek Piper claims (1994, p. 163):

> *"During Himmler's second inspection visit to Auschwitz on 17 July 1942, he witnessed the entire procedure of liquidation of one transport – from unloading the train cars to gassing (in bunker two) and removing the bodies. It cannot be ruled out that his observations resulted in the decision to cremate the bodies instead of burying them. In fact, shortly after Himmler's visit, Standartenführer Paul Blobel from Eichmann's office arrived at Auschwitz with orders to exhume all buried bodies, burn them, and scatter the ashes to prevent the possible reconstruction of the number of victims."*

Himmler's order to burn the alleged victims of "special operations" – on pyres! – is therefore supposed to have been issued *after* the decision to immediately build the crematorium – which had been triggered by "special operations." The conclusion is compelling that at the time when a new situation made this construction necessary, there could not yet have been any thought of burning gassed persons – in a crematorium or otherwise. Consequently, the "special operations" – if by this one means the gassing of human beings – could in no way have given the impetus for the rapid construction of the crematorium, but, possibly, only an expansion of the mass graves.

Indeed, there can be no doubt that the Bischoff letter indicates a direct connection between the new situation caused by the "special operations" and the immediate construction of the crematorium. But of what does this connection consist? In order to be able to answer this question, we must embed Bischoff's remarks within their historical context.

On 1 March 1942, the strength of the camp population of Auschwitz was 11,132 prisoners at the morning roll call, the majority of whom were Poles.[229] On 26 March the first "special trains" organized by the *RSHA* arrived. In March 2,909 Jewish deportees arrived, 7,762 in April, 1,000 in May, and

[229] *Stärkebuch*, analysis by Jan Sehn. AGK, NTN, 92, p. 22.

5,096 in June, amounting to a total of 16,767, of which 10,332 were men and 6,435 women. There was a corresponding increase in prisoner mortality. In March 1942 3,038 deaths were registered in Auschwitz, 2,209 in April, and in the following months the mortality climbed at an even greater rate: 3,341 deaths in May and 3,817 in June, among them 2,289 Jews in the men's camp alone, which accounted for more than 62 percent of the deaths for that month. From June 22–30, an average of 140 prisoners died each day, the highest figure (194 deaths) occurring on June 25. From 1 to 13 July, the average daily mortality rate hovered was about 130.

This already desperate state of affairs was made worse by the murderous typhus epidemic that broke out on 1 July in the communal camp of the civilian workers deployed in Birkenau[230] and very soon spread to the prisoners.[231] Under these circumstances, a further increase in mortality in the camp was to be expected. The situation became so drastic that on 23 July Höss had to impose a total quarantine on the camp to prevent the epidemic from spreading to the outside world.[232] In the month of July, 4,401 prisoners died, 4,124 of them in the men's camp alone; 2,903 or more than 70 percent of the victims were Jews.[233] Nevertheless, the "special trains" continued to arrive in Auschwitz, indeed more frequently than before: In July 11,756 Jews were received into the camp population, so that typhus was able to reap an even richer harvest than before. This explains the extremely high percentage of Jews among those who died.

The hygienic situation became even more catastrophic: The crematorium at the Main Camp had not been functioning properly since the beginning of June 1942, because its chimney was damaged. The chimney had to be removed and restored, and the crematorium went out of service at the beginning of July.[234] Therefore the dead had to be buried in mass graves, which of course further worsened hygienic and sanitary conditions in the camp.

Let us recapitulate. At the beginning of July the situation was as follows:

– Sanitary conditions were rapidly worsening.
– Mortality was rising.
– The Jewish transports were arriving at a faster pace.
– The crematorium in the Main Camp had stopped operations.

---

[230] Letter of 1 July 1942 from the official commissioner to the firms of Huta and Lenz. RGVA, 502-1-332, p. 151.

[231] As a matter of fact, typhus was already raging in the camp prior to this, as Czech indicates with her entries for 27 March, 10 & 25 May and 17 June 1942 (1990, pp. 150, 165, 171, 182). The first typhus cases seem to have been imported into the camp by a transfer of prisoners from the Lublin prison as early as 6 April 1941, however (*ibid.*, p. 57).

[232] The measure was already in preparation on the 20th. "Hausverfügung" no. 40 of 20 July 1942. RGVA, 501-1-25, p. 61.

[233] *Stärkebuch*, analysis by Jan Sehn. AGK, NTN, pp. 109f.

[234] Letter of 6 July 1942, from Pollock. RGVA, 502-1-312, pp. 29 and 31. The crematorium was most certainly taken out of operation the following day.

The first three factors were closely connected with one another: In a tragic feedback loop, the increase in Jewish transports led to a worsening of sanitary conditions and consequently to soaring mortality.

In this context, the sentence of Bischoff that is under dispute can mean nothing other than this: In July 1942, the immediate construction of the new crematorium had become an absolute necessity as a result of the unexpected and critical deterioration of health and sanitary conditions in the camp caused by the Jewish transports as described above.

As we will see in Documents 67 and 69, "special measures" and "immediate operations," equivalents for "special operations," consisted precisely in the reception and accommodation of Jewish transports.

[59] Document 64 (p. 229)

This is a letter by Bischoff dated 4 November 1942 with the subject "Construction Project VIII Up a 2." At the beginning the "Construction Project 'PoW Camp (Implementation of Special Treatment)'" is mentioned, which had the ID number VIII Up a 2.[235] The authors explain in this regard:

> *"The contingent documentation identification number (Kennummer VIII Up a 2) refers, among other things, to the construction of the crematoria and installations defined as 'for special treatment' (*für Sonderbehandlung*)."* (p. 228)

Here the authors' dishonesty is outright blatant. First they reported an insignificant document instead of an essential documentation, and they moreover give information which must be utterly incomprehensible to anyone who is not a specialist in the matter: "contingent documentation identification number (Kennummer VIII Up a 2)." Finally, as we shall see, they falsely associate the crematoria with the term "for special treatment."

On 28 October 1942, Bischoff drafted a general construction project for the Birkenau Camp titled "Construction Project PoW Camp (Implementation of Special Treatment)," bearing the construction reference number VIII Up 2 (see DOCUMENT 24). *All* structures of the camp fell within the "Implementation of Special Treatment," but contrary to the authors' mendacity, the sole facility to which the document specifically assigns the function of "special treatment," is not a crematorium, but a disinfestation facility, as I have stated already many years ago elsewhere (2004b, pp. 38-41):[236]

> *"16a) Delousing facility*
> *1. for special treatment*
> *Area: 50.00 x 20.00 = 1,000 m²*
> *Height of building: 6.20*

[235] On the meaning of this reference see Mattogno 2005d, pp. 26f.

[236] "Vorhaben: Kriegsgefangenenlager Auschwitz (Durchführung der Sonderbehandlung)." VHA, Fond OT 31(2)/8, p. 9. See DOCUMENTS 24a, 24b.

Enclosed space: 1,000.00 x 6.20 =	*6,200 m³*
Cellar section: 35.00 x 20.00 x 3.20 =	*2,240 m³*
total	*8,400 m³*
Cost for 1 m³ RM 28.00	
8,400.00 x 28.00 =	*236,320.00*
Extra charges for heating, shower	
and disinfestation facilities	*RM 73,680.00*
	310,000.00
16b) 2. For the guard troops	
Area: 12.25 x 12.65 + 12.40 x 8.70 =	*262.84 m²*
Height of building: 2.80 m	
Enclosed space: 262.84 x 2.80 = approx.	*736.00 m³*
[…]	
Costs for 1 m³:	*RM 30.00*
736.00 x 30.00 =	*RM 22,080*
Extra charges for heating, shower	
and disinfestation facilities	*RM 7,920*
	RM 30,000"

It remains to be established what the nature of this "disinfestation facility for special treatment" was.

The two disinfestation facilities mentioned are listed under the same numbers (16a and 16b) in another report of the Central Construction Office, dated 2 February 1943. Here, Facility 16b is designated a "delousing facility for the guard troops," and its dimensions correspond exactly to those stated in the project – of 28 October 1942: "12.65×12.25 + 12.40×8.70 m"; Facility 16a is called a "delousing facility for prisoners" and shows dimensions different from those given in the project: 48 m × 12 m + 34 m × 12 m. This reduction in volume can be explained by a shortage of building materials, for the document referring to this is, in fact, titled "Auditor's Report on Saving Building Material."[237] The new dimensions of the installation agree perfectly with those of Drawings No. 1841 of the Central Construction Office of 24 November and No. 1846 of 25 November 1942, in which the "Disinfection and Delousing Facility in the PoW Camp" is depicted and which reflect the original project of the Birkenau *Zentralsauna* (blueprints reproduced in Pressac 1989, pp. 68f.).

The "Situation map of the prisoner-of-war camp" of 6 October 1942 confirms this situation explicitly: The rectangle representing the so-called *Zentralsauna* bears the designation "16a disinfestation."[238] Thus the "disinfestation facility for special treatment" of the project of 28 October 1942 was noth-

[237] "Prüfungsbericht Nr. 491 über Baustoffeinsparung gemäß G.B.-Anordnung Nr. 22." RGVA, 502-1-28, pp. 234-238. The two facilities are mentioned on p. 236.

[238] VHA, Fond OT 31(2)/8.

ing other than the famous *Zentralsauna*, the most important hygienic-sanitary facility of the entire Auschwitz-Birkenau camp complex. Special treatment – *Sonderbehandlung* – consisted therefore in carrying out hygienic-sanitary measures.

The authors' dishonesty is also evident from the fact that their Document 28, "Structures of the Central Construction Office of the *Waffen*-SS and Police Auschwitz in the 3rd budget year of war," which in paragraph 21 mentions five barracks for special treatment, explicitly refers to the "disinfestation facility for special treatment" in the section for the PoW camp Birkenau. A different version of the document, dated 15 November 1942, reported under the construction reference number "GB Bau VIII Z a 1(1)," Point 21, "5 barracks for special treatment,"[239] and under the construction reference number "G.B.-Bau Nr. VIII Up a 2", Point 31, "disinfestation facility a) f. special treatment b) f. the troops (sauna and disinfection)." Point 30 mentions "4 crematoria and 4 morgues,"[240] which shows that the crematoria were not designated for "special treatment," and at the same time this exposes the authors' lie and explains the reason for their calculated omission.

[60] Documents 65 (p. 231) and 68 (p. 237)

These two documents concern the same issue, so I examine them together. The first is a "list of concrete requirements for the month of January 1943" written by Bischoff on 20 November 1942. The estimated need was 300 metric tons, 150 of them for Construction Project VIII Up a 1, and 150 for Construction Project VIII Up a 2. Point 2) clarifies:

> *"a) SS accommodation and CC Auschwitz – VIII Up a 1*
> *b) PoW Camp Auschwitz O/S – VIII Up a 2 (implementation of special treatment)."*

The authors limited themselves to stating that "the special treatment operation was underway on the grounds of the Birkenau camp (*Durchführung der Sonderbehandlung*)" (p. 230), but carefully avoid explaining why this "special treatment" operation required 150 tons of cement (just like the Auschwitz Main Camp, where that operation was not in progress). What is the relationship between these 150 tons of cement and the alleged gassings in the "bunkers"?

Document 68 is a letter by Bischoff of 9 January 1943 addressed to the camp commandant listing the camp's various construction offices subordinate to the Central Construction Office. Birkenau is listed there as follows:

> *"3. Construction Office of the Prisoner-of-War Camp (implementation of special treatment) Auschwitz."*

---

[239] RGVA, 502-1-85, p. 114.
[240] RGVA, 502-1-85, p. 119. See DOCUMENT 25.

The authors do not comment on this, but merely point to the presence of the expression "implementation of special treatment," as if that were enough.

As indicated earlier, they have dishonestly concealed from the reader that the special treatment referred to in these documents had nothing to do with any mythical homicidal gassings, but with sanitary and hygienic measures. This fact and other documents ignored by the authors allow us to further deepen our understanding of the meaning and significance of this "special treatment."

The organizational chart for the Central Construction Office created by Bischoff in three versions in January 1943 gives the tasks of the Birkenau Construction Office as follows:

1) "Construction Office of the Prisoner-of-War Camp (implementation of special treatment)"[241]

2) "Construction Office of the Prisoner-of-War Camp (implementation of special construction measures)"[242]

3) "Construction Office of the Prisoner-of-War Camp (implementation of special operation)"[243]

In the latter document we also read:[244]

> *"At the present time, the completion of the PoW camp (special measures) is most urgent."*

These documents prove that "special treatment" ("*Sonderbehandlung*"), "special construction measure" ("*Sonderbaumassnahmen*") and "special operation" ("*Sonderaktion*") were one and the same thing, none of which referred to the alleged homicidal gassings.

The equivalence of these terms is further confirmed by other documents ignored by the authors:

– Bischoff's letter to the Contingency Office of the General Plenipotentiary for Regulating the Construction Industry (Albert Speer; *Kontingentstelle des G.B. Bau*) of 19 December 1942, in which he complains that Construction Project VIII Up a 2 (Birkenau) had received an allocation of 2,800 tons of cement for the months of November and December, but that only 1,800 had been delivered. The letter has as its subject: "PoW camp Auschwitz, special construction measures."[245]

[241] "Geschäftsverteilungsplan der Zentralbauleitung der Waffen-SS und Polizei Auschwitz und der unterstellten Bauleitungen." RGVA, 502-1-57, p. 316; reproduced in Mattogno 2004b, p. 129.

[242] Organization chart of the *Zentralbauleitung* on key personnel for the operations of each individual *Bauleitungen* (the first page of this document is missing). RGVA, 502-1-57, p. 310; reproduced in Mattogno 2004b, p. 130.

[243] Letter by Bischoff to Kammler of 27 January 1943. RGVA, 502-1-28, p. 248; reproduced in Mattogno 2004b, p. 131.

[244] *Ibid.*, p. 249.

[245] RGVA, 502-1-319, p. 49.

– Bischoff's letter to Kammler of 14 May 1943 with the subject "Carrying out of the special operation – procurement of material," regarding the consignment of various types of pipes.[246]
– SS-*Untersturmführer* Pollock's request to the contingency office of the *GB Bau* from 14 March 1943 concerning "Construction project Prisoner-of-War Camp – implementation of special treatment." It mentions an allocation of 459,111 kg of iron for the second quarter of 1943; 29,940 kg of construction iron (*Baueisen*) were destined for Crematoria II and III, 15,316 for Crematoria IV and V. The remaining quantity was for five other structures, including the sewage-treatment plant and the fresh-water supply system (*Wasserversorgung*).[247] Which demonstrates that the crematoria did not have any special relevance in the context of special treatment, since the term referred to the entire Birkenau Camp.
– Kirschnek's already-mentioned "Activity report of the Construction Office of the concentration camp and agriculture" for the period from 1 July to 30 September 1943 contains a section headlined "Work carried out in the PoW camp – deployment of local construction office for special construction measures"; the construction of five wash and toilet barracks is listed for Construction Sector I (*BW* 6-7A); for Construction Sector II the following items are listed: four storage barracks (*BW* 14), 12 wash barracks (*BW* 6b), 21 toilet barracks (*BW* 7b), 60 housing barracks for prisoners (*BW* 3d), the disinfestation facility (*BW* 32, the *Zentralsauna*), the delousing facility in the gypsy camp (also *BW* 32) as well as 11 infirmary barracks with annexes (*BW* 12a); for Construction Sector III the document lists only the fence (*BW* 24) and drainage ditches E, F, H, I (*BW* 18).[248]
– The "Report on requirements for thick, medium and thin sheet metal for the IV. Quarter of 1944" contains two references to Construction Project VIII b Up a 2003 "Auschwitz CC II special measures."[249]

[61] Documents 66 (p. 233), 71 (p. 249) and 72 (p. 251)

Document 66 is a letter by Bischoff to Office C/V (Central Construction Inspectorate) of the SS-*WVHA* dated 29 December 1942 with the subject "Labor Deployment Auschwitz. Reimbursement of canceled labor hours due to a decreed special operation." The text says:

> *"The Central Construction Office hereby reports that inmates and civilian workers employed at the individual construction sites could not be deployed during four days as a result of carrying out a special operation.*

[246] RGVA, 502-1-83, pp. 315f.; reproduced in Mattogno 2004b, pp. 133f.
[247] RGVA, 502-1-319, p. 15.
[248] RGVA, 502-1-27, pp. 6-8.
[249] RGVA, 502-1-317, p. 36.

> *Advice is requested as to which titles and chapters these costs are to be allocated to."*

In their English caption the authors speak of "interruptions of work by prisoners and civilian workers resulting from special operations"[250] (p. 232), evidently having in mind the "constant labor interruption" mentioned in Document 59.

In this context, they omit a well-known document from an earlier date which clarifies the entire affair. On 18 December 1942 Bischoff sent a secret telegram to Kammler on the expected completion of the crematoria in which he conveyed the following:[251]

> *"In the month of December work had to come to a standstill for several days due to delousing and disinfestation. Likewise, a Gestapo special operation for security reasons encompassing all civilian workers has been underway since 16 December. Due to the imposition of a camp lock-down, the civilian workers have been unable to leave the camp for six months. For that reason, a grant of leave from 23 Dec. 1942 to 4 Jan. 1943 is absolutely essential."*

Pressac commented on this as follows (1994, p. 73):

> *"The revelation* [postponement of vacations for civilian workers] *embittered the civilian workers, since they had been stuck in Auschwitz for five months. It is not known exactly what happened next, but on the 17th and 18th of December none of the civilian workers showed up at the building site, and work didn't resume until the 19th. On the 17th a spontaneous strike is supposed to have occurred, that led to the intervention of the camp Gestapo (the political department), in order to bring it under control. This intervention was designated a 'special action for security reasons.' (*Sonderaktion aus Sicherheitsgründen*). The civilian workers are supposed to have been subjected to interrogation by the political department, which wanted to learn the reason for the strike."*

Document 72 is a simple reminder letter by Bischoff from 28 January 1943, also with the subject "Labor Deployment Auschwitz. Reimbursement of canceled labor hours due to a decreed special operation," to find out which title and chapter the costs should be allocated to that had been caused by the special operation conducted by the camp's Political Department. The reference of the letter shows that Bischoff had already written a first reminder on 29 December 1942.

Document 71 is a letter from the company Baugeschäft Anhalt – Hoch-Tief-Eisenbetonbau of Berlin to the Central Construction Office dated 22 Jan-

---

[250] In the Polish original "*przerwa*," interruption, and "*w wyniku realizacji akcji specjalnei*," "as a result of carrying out of a special operation."

[251] APMO, BW 30/27, p. 17.

uary 1943. It lists the costs of the company's activities during the construction of various structures at Auschwitz, which also includes:

> *"Special operation, department for labor deployment, Auschwitz O/S on 11 Jan. 43 in the amount of RM 753.29 – 12 daily-wage slips."*

According to the authors, this referred to "work done on January 11, 1943 at a place where a special operation (*Sonderaktion*) was underway" (p. 248).

Their concealing the telex dated 18 December 1942 happened in my opinion more likely due to deliberate dishonesty than to simple historical-documentary ignorance. In fact, Document 71 is closely linked to the special operation conducted by the Political Department of Auschwitz. That special operation was triggered by the strike of the civilian workers, which in turn caused the interruption of work for four days, resulting in financial damage to their employers. With the letter of 22 January 1943, the company Baugeschäft Anhalt therefore simply sought reimbursement of the 753.29 RM lost during the four days of forced labor standstill. The date of 11 January 1943, which is also given for two other entries on that document not mentioning any special operation, is probably that company's reference to an administrative act by the Central Construction Office, with which the employer's right to a reimbursement had been recognized. Subsequently Bischoff urged Kammler precisely because of this request (and possibly those of other companies) to inform him how he should account for – and then also pay – these expenses.

[62] Document 67 (p. 235)

This is a letter by Bischoff to the camp commandant dated 7 January 1943. The first paragraph states:

> *"18 guards for wagon transports to the PoW camp are urgently needed for the special measures to be carried out (accommodating the announced transports of 10 to 31 January 1943). Should the assignment of the guards not be possible, then the commandant's task cannot be carried out. The construction materials are required for setting up the stoves."*

The document clearly says that the special measures consisted in *accommodating* the transports, not in *killing* them in "gas chamber." The 18 guards had to supervise the trucks used to transport construction materials for heating stoves to Birkenau, which evidently were to be installed in the barracks set up to accommodate the announced transports.

In their mendacious comments, however, the authors distort the meaning of the document, stating that the SS guards were meant to supervise "the transport of materials for the construction of objects serving special actions"! (p. 234, Polish text).

A week later, on 14 January 1943, the British intercepted the following message illuminating the letter in question:[252]

> *"From WVH*[A] *SS, BERLIN, to CC. AUSCHWITZ, outpost FLUSSZNIES* [sic].
> *Re.: Stoves for barracks. Stoves are wrapped and ready for shipment at ORANIENBURG. Shipment follows by railway right after approval of waybill; pickup therefore not needed.*
> *SS WVH*[A] *BERLIN, the Head of Office W I, p.p. signed SCHWARZ, SS Hauptsturmführer."*

[63] Document 69 (p. 241)

This is a telex by Bischoff to the head of Office B/V (transports) of the SS-*WVHA*, SS-*Sturmbannführer* Rudolf Scheide, dated 15 January 1943, which contains the following request:

> *"Referring on the one hand to the above-mentioned letter, and on the other hand with regard to the instant operation ordered by the Reichsführer SS – accommodation of 47,000 Jews within a very short period of time – this office once more requests the immediate assignment of 6 dump trucks in order that the construction of the respective accommodations can be finished on schedule (until 31 Jan. 43), which is technically impossible for this office with the motor pool currently available to it."*

This document fully confirms Document 67: special measures and immediate operation meant accommodating Jewish transports. We have seen above that special treatment, *inter alia*, expressly referred to the disinfestation and disinfection facility called *Zentralsauna*.

The authors butcher the document's self-evident meaning by speculating:

> *"This might have been connected with preparations to deport and exterminate Jews from Greece, whose concentration in the ghetto at Salonika began a month earlier. A total of 47,200 Greek Jews were deported to Auschwitz from March to June 1943."* (p. 240)

Such an explanation can only be the result of deliberate deceitfulness. Their conjecture actually doesn't even make sense, precisely because the deportation considered by the authors took place between March and June 1943, while the document in question mentions a "very short period of time" and a deadline "until 31 Jan. 43."

In this context another pathetic ploy of the authors should also be noted. From 20 March to 18 August 1943, 18 Jewish transports arrived at Auschwitz from Greece bringing 48,533 people into the camp. In order to make that number match the figure of 47,000 given in the telex, the authors ignore the last transport of 18 August 1943 with 1,800 people. But even then their figure

---

[252] TNA, German Police Decodes No. 3 Traffic: 14.1.43. I B Traffic. ZIP/GPDD 358b/22.1.43.

of 47,200 deportees is wrong, apparently forcibly adjusted for the same reason, because the total number of deportees from the remaining earlier transports is 46,733 (Czech 1970, Table outside of text).

It is clear that the content of the document in question refers to the telex sent on 16 December 1942 by the Gestapo Chief Heinrich Müller to Himmler, which reads:[253]

> *"In the course of the increased recruitment of manpower into the concentration camps, as ordered to occur by 30 January 1943, the following may be applied in the Jewish sector:*
> *1. / Total amount: 45,000 Jews. –*
> *2. / Start of transportation 11 January 1943 –*
> *End of transportation: 31 January 1943 – (In the period from 15 Dec. 1942 to 10 Jan. 1943, the* Reichsbahn *is unable to provide special trains for the evacuation due to increased* Wehrmacht *holiday traffic.) –*
> *3. / Breakdown: the 45,000 Jews are divided up in 30,000 Jews from the Bialystok district – 10,000 Jews from the ghetto Theresienstadt. Of them 5,000 employable Jews, who were employed so far for minor jobs in the ghetto, and 5,000 Jews, generally unable to work, even those over 60 years old, in order to reduce the camp's overly high occupancy on this occasion in the interests of expanding the ghetto.*
> *For this I ask to grant a special permission. As before, only those Jews would be included in the evacuation who have no special relationships and connections and who have no high decorations. – 3,000 Jews from the occupied Dutch areas. – 2,000 Jews from Berlin = 45,000. The number of 45,000 includes unemployable (underscored) relatives (elderly Jews and children). When applying conducive criteria while examining the Jews arriving at Auschwitz – at least 10,000 to 15,000 laborers (underscored) arise from this."*

Evidently, Himmler had increased the number of these deportees to 47,000. We therefore leave aside the difference of 2,000 deportees, which is irrelevant in the context of this argument. Since the above-mentioned 45,000 deported Jews could contain 30,000-35,000 unemployable individuals, the document shows that these were not slated to be gassed. Otherwise Himmler would have ordered only an "immediate operation – accommodation" for 10,000-15,000 Jews fit for labor, not for all 47,000.

According to the *Auschwitz Chronicle*, between 11 and 31 January 1943, 51,417 deportees arrived at Auschwitz, of which 43,764 were gassed and just 7,653 registered, less than 15%! This is in total contrast to Himmler's order to accommodate 47,000 inmates at Auschwitz, and to Bischoff's concern to prepare the necessary accommodations for *all* of them on time.

---

[253] PS-1472. IMT, vol. XXVII, pp. 252f.

[64] Document 70 (p. 245)

This is the well-known file memo written on 22 May 1943 about a meeting with Kammler in the offices of the Central Construction Office which occurred during the previous day. The authors interpret it this way:

> *"On the first page, in the section presenting the founding and development of the Auschwitz camp, there is information that the operation to solve the Jewish question is currently underway there (*Dazu kam in letzter Zeit die Lösung der Judenfrage*)."* (p. 244)

Even this comment is surprisingly insidious. I reiterate here my analysis of this document as presented in one of my earlier studies (2004b, pp. 51f., 58) and elaborate on it further.

On 22 May 1943 Höss gave a speech to the head of Office Group C of the SS-*WVHA*, Hans Kammler, as well as other functionaries, in which he outlined the origin and development of the institutional missions of the camp:[254]

> *"In the year 1940, the Auschwitz Camp came into existence in the delta estuary between the Vistula River and the Sola River after the evacuation of 7 Polish villages, through the reconstruction of an artillery-barracks site and much construction of extensions, reconstructions and new buildings, utilizing large quantities of material from buildings that had been demolished. Originally intended as a quarantine camp, this later became a Reich camp and thereby was destined for a new purpose. As the situation grew ever more critical, its position on the border of the Reich and G.G.* [General Gouvernement] *proved especially opportune, since the filling of the camp with workers was guaranteed. Recently and in addition to that came the solution of the Jewish question, which required creating the means to accommodate 60,000 prisoners at first, which increases*[255] *to 100,000 within a short time. The inmates of the camp are predominantly intended for the industries which are locating in the vicinity. The camp contains within its sphere of interest various armament firms, for which the workers are regularly provided."* (p. 85)

The "solution of the Jewish question" thus required no extermination or crematorium facilities, but instead measures for the construction of accommodations for 100,000 prisoners: The supposed homicidal function of the camp was not only not a priority, it did not exist at all!

Throughout the document there is not the vaguest hint at deportees being killed; in fact, it insists on the improvement of the camp's hygienic and sanitary conditions. Point 2 of the speech, headlined "Large PoW camp" (*Grosslager K.G.L.*), reports (p. 86):

---

254 *Aktenvermerk* of 22 May 1943. RGVA, 502-1-26, pp. 85-87.

255 The past tense ("increased"), which appeared originally in the text, has been changed to present tense. In this context, this present tense has the meaning of a future tense.

> *"But due to various dangers of epidemic disease, it is at present essential to take immediate measures for the improvement of the existing facilities."*

The section on the "PoW camp" laments the poor hygienic conditions of the Birkenau Camp, the lack of a general drainage system and of water supply, which created the danger of epidemics breaking out. The garrison physician declared that

> *"the huge danger of epidemics caused by the admissions from the East cannot be coped with properly owing to the scant control possibilities due to a lack of water and the lack of allocated quotas for the necessary drainage system."* (p. 86)

There was also the problem of the birth of 50 children per day in the gypsy camp, and the problem of caring for 10,000 sick inmates with very primitive medical facilities. Therefore, the physician concluded, the increase of the camp's strength to more than 100,000 prisoners would be catastrophic (p. 87).

At this point in time, however, Dr. Wirths complaints had already been considered, because on 13 May, under the program for the improvement of the Birkenau Camp's hygienic installations as inaugurated by Kammler on 7 May, Bischoff had authored a "report concerning the division of labor for the instant program in the POW camp Auschwitz," which assigned to his subordinates their respective tasks in the scope of that program.[256] Furthermore, as I already mentioned, starting on 16 May at the latest, the reports to Kammler began about the "special program in the PoW camp Auschwitz"[257] or on "special measures in the PoW camp."[258]

These special measures, as I mentioned above, were at times also called "immediate program" (*Sofortprogramm*), "special construction measures" (*Sonderbaumaßnahmen*) and "special operation" (*Sonderaktion*). This program also involved the crematoria of Birkenau, but not for "gassing" any detainees. The above-mentioned report of 16 May states in Step 6, "disinfestation facility":[259]

> *"For the disinfestation of the clothing of prisoners, a disinfestation facility is planned in each of the individual camp sectors of* BA *II. In order to be able to perform a flawless body delousing of the prisoners, hot water heaters and boilers are being installed in the two existing prisoner baths in* BA *I, so that hot water is available for the existing shower facility. It is*

[259] RGVA, 502-1-83, p. 311. On these real showers planned but only partly realized in Crematoria II and III at Birkenau see the documentation I have collected in 2009, pp. 138-142 (2019, pp. 134-140).

> *further planned to install heating coils in the waste incinerator of Crematorium III in order to obtain water for a shower facility to be built in the basement of Crematorium III. Negotiations to perform the construction for this installation were held with the Topf & Söhne firm."*

How can this project be reconciled with the alleged criminal purpose of Crematorium III?

[65] Document 73 (p. 253)

Even this is a well-known document which was already published by Pressac (1994, Document 21). It is a map with the headline "Overview of surveying the area of interest of CC Auschwitz" from 2 June 1943, in which an area is marked as an "off-limits zone."[260] I have thoroughly analyzed this document elsewhere in order to refute the French historian's interpretation.[261] Hence I reiterate and expand on the main parts of that elaboration, and to make it understandable to the reader, I again reproduce this map (see DOCUMENT 26).

The map in question was drawn for topographical and cartographical reasons. In this respect the Central Construction Office had already become active in late 1942.[262] Preliminary work on the survey grid of the zone had been done by 13 January 1943, but other work still remained to be done.[263] The map has a direct link with the enlargement of the area of interest of Auschwitz Concentration Camp, which took place the day before the map was drawn. It was announced in the *Amtsblatt der Regierung in Kattowitz*, the official journal of the Kattowitz region, which gave a detailed description of the new limits of the "area of interest."[264]

The "off-limits zone" had a clear relationship with the various camp lock-downs decreed by Höss on account of the typhus epidemics. For example, in 1943, on 9 February, Höss gave a Garrison Order No. 2/43, in which he announced that the head of Office Group D of the SS-*WVHA*, SS-*Brigadeführer* Glücks, had ordered a "total lock-down of the camp" because of the spread of typhus cases.[265] In Garrison Order No. 3 of 14 February, Höss defined the limits of the "off-limits zone for the total camp lock-down":[266]

> *"In reference to Garrison Order 2/43* [recte: 25/42] *cited in Garrison Order 25/42* [recte: 2/43], *the former will be modified in the sense that the fol-*

> *lowing area is defined as an off-limits zone for the total camp lock-down in accordance with indications on the map of CC Auschwitz area of interest: The off-limits zone is represented by the CC Auschwitz area of interest, limited in the north, west and east by the Vistula and/or Sola rivers* […]*."*

This having been clarified, let us now look at the map of June 2, 1943. The map shows, within an obliquely shaded area, a white zone labeled "off-limits zone" and "Birkenau PoW camp." The latter zone corresponds more or less to the Birkenau Camp, whereas the one labeled "off-limits zone" extends some 950 m toward the Vistula River, north-northwest from the left side of the camp. If the "off-limits zone" was no larger than this, it included neither the location of the alleged "bunkers" nor their mass graves. My DOCUMENT 27 in the Appendix is a superimposition of the map of the Birkenau Camp on the map of 2 June 1943. The zones marked by circles indicate:
